Many of my photographs have a deeper meaning than the untravelled will perceive. Few people, unless they have lived in Japan and closely studied the people, would understand my study of a lotus garden. Who that has not sounded something of the soul of these people could know anything of the sorrows that often wrings the heart of the Japanese as he visits the garden where grows the flower that sinks into itself at evening hour. To the Japanese the lotus is the emblem of all that is best in womanhood; it is also the emblem of that grim reaper whose path is wet with tears. Early in the morning, long before the sun has risen, you may see people astir in the Garden of the Lotus. Some are flower worshippers; others, as their faces show, are nursing sorrow in their hearts. They have come to see the beautiful flowers open as the sun rises in the sky. The peace and restfulness of such places, where herons and cranes wander undisturbed, and the subdued demeanour in which people visit them, I have tried to convey. The attitudes of the girls are true characteristic Japanese attitudes, and that of the little maid stooping to watch the great bloom open its lovely petals to the rising sun, I shall never improve on, though I hope some day to make another study of this subject.

I was told that this picture was considered by the critics as too spotty. Thus is the outcome of years of study of a foreign people, and many days of work in finding and bringing together the various parts of the subject, scoffed at by those who do not understand it. The picture that to the Japanese had meant so much, meant nothing to the Englishman at all.

Also, I would say that the two men engaged in carving ivory are the most famous artists in the world in their line. And the old potter is no mere wayside thumper of wet clay such as old Omar saw, but one in whose hands the "shapeless, lifeless clay" rises up as few can make it rise, even in this land of potters.

Likewise, too, the study of Mr. Namikawa feeding his carp is a glimpse into the home life of a man who has brought the art of cloisonné making to the highest point of perfection it has ever reached in any land. All the cloisonné vases presented by the Emperor to foreign potentates are made by Mr. Namikawa. So also most of my studies have a meaning, and on them hangs a tale.

I would like, gentlemen, to express my thanks to my unknown champion in your issue of September 25, "Anti-Progress." My heart warms towards him. His appreciation of the difficulty of showing Oriental sunlight and atmosphere shows how well he understands the subject. In my case the difficulty is not confined to getting out a single exhibition print, which may have demanded many days of work to make it a success, and the discarding of dozens of unsuccessful efforts, but in so making my negatives that they may be printed from by the gross, and that each carbon print shall be identical in merit with all others. The samples exhibited by Messrs. Raines are no better than any of a hundred prints in my portfolio made by them.—Yours very truly,

H. G. PONTING.

## Answers to Correspondents.

- \**All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C."* Inattention to this ensures delay.
- \**Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*
- \**Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.*
- \**For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.*

### PHOTOGRAPHS REGISTERED:—

**LICENCE.**—I am making photographs and dry mounting them on art mounts. I supply these to the shops wholesale, and have no shop myself. Should I require a licence from the local authorities to carry on this work, and also is it usual to obtain licence for doing outdoor photographic postcards in my garden? I do no canvassing.  
—J. T.

Certainly not. You require a licence only when you actually hawk goods or come within the scope of the Pedlars Act.

**STRIPPING CINEMATOGRAPH FILM.**—Would you kindly let me know if it is possible to get cinematograph film (exposed and developed) away from its support without injuring the support?—J. WALLIS.

We can only advise you the process of using formaline and caustic soda, followed by an acid, as given in the "Almanac," page 808.

H. W. GAULD.—1. There is not a great difference between the most rapid of the leading makers. All, we should say, are a little ahead of those you name as regards speed. 2. Fritzsche A. G., 90, Ritterstrasse, Leipsic, and Oeser and Co., 19/20, Bahnstrasse, Schöneberg, Berlin.

H. B. MILES.—1. Ilford, Lumière, and Wratten plates are all used for the purpose. 2. The usual method is adopted. 3. Apply to Dawbarn and Ward, 6, Farringdon Avenue, London, E.C. The price is 6s. 4. Marion and Co., 22/23, Soho Square, London, W., or W. Tylar, Ltd., High Street, Aston, Birmingham. They are not likely to be smaller than 10 x 8, more probably 12 x 10 or 15 x 12.

**ARC LIGHTING.**—1. What would be the most suitable electric lamp for use in a studio of the following dimensions:—Length 24 feet, width 11 feet 6 inches, height to eaves 8 feet, ridge roof 12 feet from floor at highest point, which is in centre of studio? 2. How high above the sitter's head, say of a full-length standing, would it be necessary to place the light in order to get a well-lit picture? I may add the current here is alternating and voltage 105.—DARKSLIDE.

1. We should recommend one of the smaller sizes of enclosed arc lamps. 2. So that the light reaches the head at an angle of 45 deg. This would mean 8 to 10 feet from the floor with a sitting figure. 3. The lamp would be supplied for your current and voltage. Very much depends on the way the lamp is fitted in your studio and the method of distributing the light.

**AN AGENCY QUESTION.**—My agents (Messrs. — and Co.) engaged through an advertisement in your columns an assistant operator,

who could finish in black and white and retouch. They engaged a Mr. —, who in due course arrived in India. After being with me three days he told me that my agents said his salary would start from the day he signed the three years' agreement. I replied that if they had said so (although I scarcely thought it fair, as I had to pay his passage and expenses up to the time he arrived here), I should certainly give him the amount. I had not received the agreement or any advice as to what he had been paid at home, so I gave him part of the amount in advance and promised, on receiving advice and the agreement from my agents, I would act up to the terms and abide by what my agents had promised him. He worked for me a fortnight and then disappeared. 1. Now, can I claim the passage-money and all expenses I have been put to? I would be obliged if, in your "Answers to Correspondents" column, you would mention the facts. Of course, I see my agents ought to have got at least a good reference before sending the man out. 2. Can I hold my agents responsible for the amount lost by not getting a satisfactory reference for a man they sent out to me?—F. B. STEWART.

1. We should say that you could, unless the man will serve the three years according to the agreement. 2. This is doubtful, as no doubt your agents had what purported to be satisfactory references when they engaged the man. If you can prove they were negligent in the matter, which may be difficult, you might possibly recover.

**DEVELOPMENT.**—In a recent issue I read some notes on "A Reliable Method of Development," by G. R. Henderson. I have tried the method on two occasions with several negatives and the results have been perfectly satisfactory as regards development, but I think every negative showed a tendency to frill—a trouble which I rarely experience with other developers—and in some cases the frilling was exceedingly bad. I know very little about chemistry, but am very careful about chemicals, weigh the quantities carefully, and I am very particular about other matters of detail, and therefore I write to ask if you can explain the cause of the frilling. I may mention that I used alum potass. crystals (which I had in stock) after inquiring of a chemist and being informed by him that that kind of alum would be correct. I cannot help thinking that something must have been too strong, as although in one or two cases I left the negative in the clearing bath 15 or 20 seconds and in the intensifying solution about a couple of minutes, in other cases I did not leave it in so long.—PYRO-AMMONIA.

The author of the article writes as follows:—I have gone over the formula given and find it correct in every way. I have also just finished developing twenty half-plates by this method, and none of them shows the slightest sign of frilling ("Royal Standard" and Mawson plates). The citric acid may be reduced to 3oz. instead of 1oz.; but I fear the querist is not using a plate which will take kindly to pyro-ammonia. I never have any trouble with frilling, excepting, perhaps, in very hot weather. I could, however, mention two or three makes of plates which would frill every time ammonia was used in the developer, but which would take pyro-soda kindly.

**SEPIA TONES ON C.C. PAPER.**—I should be much obliged if you can give me method for obtaining sepia tones on Aristo C.C. I am well up in gold-platinum baths, but fail to get a good sepia.—H. WEST.

Wash prints in three changes of warm water and place in:—Ammonia 1 drachm, warm water 20 oz., until they become lemon yellow. They are then again washed in three changes of water, and toned for about one minute in a gold-borax bath containing gold chloride 2 grs., borax 90 grs., water 20 oz.

**ENQUIRER.**—We should recommend either No. 1 or No. 3, and to distribute the light partly by reflection and partly by diffusion. If you have a large studio and plenty of height use the larger size and remember that for group work you must use more front light in order to get both sides of the group fairly equally lighted. The usual difficulty is to get the lamps high enough in many small studios.

**LENS QUERY.**—Could you advise me what make of lens would be most suitable for taking full lengths (cabinets and postcards) in gaslight. The lens I am now using does not seem right, as when the face is in focus the body is quite in a mist, and does not show

the dress except as a dark mist. Would this be a bust lens only? I bought the lot from — new a short time ago.—K. E.

Any good cabinet lens of 11 or 12 inches focus will take full-length cabinet portraits in good focus from head to feet. An ordinary half-plate portrait lens usually has too round a field to do this satisfactorily. You say you are using gaslight as an illuminant, and we rather suspect that your trouble proceeds more from unequal lighting of the figure than from the lens.

**EMBOSSING PRESS.**—Can you tell me through the medium of your valuable columns where I could purchase a press for embossing name and trade on postcards, etc., to show in relief?—P. H. H.

Fallowfield, 146, Charing Cross Road, London, W. See also "New Apparatus" this week.

**COULD** you tell me if there is any chance of work in Australia for artists (B. W. or oils), either in a situation or start in own business?—E. W.

From what we can gather, conditions in Australia are very similar to those here.

**TRANSFER COLLODION.**—Can you give me a formula for transfer collodion, and where suitable gun-cotton is obtained?—TRICOLOUR.

Transfer collodion and enamel collodion are much the same thing. A good formula for either is: Soluble pyroxyline, 2 drachms; sulphuric ether, 10 oz.; alcohol, 10 oz.; glycerine,  $\frac{1}{2}$  drachm. Methylated ether will do, so will methylated alcohol, provided the strength of the latter is not less than s.g. .825.

**MISCELLANEOUS.**—1. Is there any serious objection to the one-exposure tricolour camera, with two plate glass reflectors, mentioned in the "B.J." a few weeks ago? 2. In this week's issue, the right-hand photo-micrograph of whalebone is reversed. Is this done in the printing, or was the section taken through the slide in one case?—TRICOLOUR.

1. The camera is perfectly satisfactory when properly adjusted. 2. We believe not; the originals were enlargements from the negatives and it is possible that one was made reversed inadvertently.

**RUBBER STAMP INK.**—I shall be much obliged if you would kindly give me in your "Answers to Correspondents" column a recipe or formula for making ink suitable for using with an indiarubber stamp, sepia in colour, to match carbons or sepia platins.—P. S. H.

Boiling distilled water, 10 oz.; glycerine, about  $\frac{1}{4}$  oz.; treacle, about  $\frac{1}{4}$  oz.; aniline dye, 900 grs. A dye or mixture of dyes of suitable colour must be used, but we fear you will have some difficulty in matching the tissues or prints. Better apply to Messrs. Mawson and Swan, Mosley Street, Newcastle-on-Tyne, or the Vanguard Co., Maidenhead, for suitable dyes.

**BROMIDE PRINTS.**—1. Will you kindly tell me how to prevent the black markings on glossy bromide postcards? Or if it can be prevented the easiest method to remove them. 2. I cannot get the cards to tone in the hypo-alum bath. They are the commercial postcards. Can you explain how this is?—STEP.

1. Methylated spirit, applied with cotton-wool, will generally remove the marks. You had better change to a paper less liable to give them. 2. Some few papers will tone readily in hypo-alum. We advise you to select a brand for which sulphide toning is recommended.

**DOS SANTOS LEITAO (LISBON).**—1. Alkaline solutions (developers, etc.) should not be used in zinc vessels. Porcelain or nickelled metal should be used. 2. The best mixture is a strong shellac solution, several coats thinly applied; or one of asphaltum, 4 oz.; pure rubber, 30 grs.; mineral-naphtha, 10 oz.

**GLOSSY BROMIDES.**—I should be glad if you could answer these questions for me in your paper. I often require to print 1-1 negatives of machinery, etc., on glossy paper for reproduction in magazines or catalogues. I have no proper water supply in my dark room, and hence the washing between developer (amidol) and fixing is rather scamped, which results in occasional yellow stains, as I am generally pressed for time with a dozen or eighteen prints to do at a time. 1. Is there any clearing bath that I could use between development and fixing to take the place of washing, which would act (a) as a quick stop to the developer; (b) to remove or diminish the surface markings, which I find a great trouble at present; (c) to obviate all risk of

yellow stains. It seems to me that something containing soda sulphite, an acid, and potass iodide might be useful, but my experiments have not met with success. 2. What do you recommend as the best formula to use with amidol on Nikko paper? I want blue-black tones, strong contrasts, quick development, capable of being used for several prints in succession. I use at present, but am not quite satisfied with soda sulphite,  $\frac{1}{4}$  oz.; amidol, 20 grs.; water, 4 oz.; no bromide.—AMIDOL.

1. We should recommend you to use an acid fixing bath and plenty of it, keeping the print fully immersed. This should prove better than an intermediate bath. 2. We should advise you to try the metol-hydroquinone developer of the makers for greater vigour, blue-black colour, and greater speed.

**VARIOUS.**—1. I have a Beck whole-plate "Isostigmat" lens,  $9\frac{1}{2}$  in. focus. The back component gives an extension of  $17\frac{3}{8}$  in., and the front  $11\frac{1}{2}$  in. Might I ask if you will be so good as to give me the F. values of each? 2. Will you also kindly inform me what the Watkins P number would be for a plate 100 H. and D. and one 150 H. and D., and if the greater speeds would be proportional and *vice versa*.—OPTICS.

1. The apertures are proportional (near enough) to the focal lengths. You do not say what the working aperture of the complete lens is, but when using the back component you must multiply the F number by 2 ( $\frac{17\frac{3}{8}}{9\frac{1}{2}}$ ) and when using the front

lens by  $1\frac{1}{4}$  ( $\frac{11\frac{1}{2}}{9\frac{1}{2}}$ ) approximately. 2. About 150 and 230 Watkins respectively. In the case of these two speeds, a fairly correct rule is that the Watkins number is  $1\frac{1}{2}$  times the H. and D. number.

**F. BROMHEAD.**—As the plates have not yet been placed on the market your only course is to apply to the Thames Colour Plate Co., 254A, High Holborn, London, W.C.

**PREPARING PORCELAIN.**—I shall be glad to know through your columns this week how to prepare a porcelain to be painted in oil (bromide basis). I fear that without some sort of preparation the oil colour will sink in and look dull.—J. FLATMAN.

The picture will require no preparation at all. Oil colour will not sink into a gelatino-bromide print on glass as it might do on paper.

**LENS FOR ENLARGING.**—Could you tell me of a cheap form of lens of short focus that would do for general copying with a camera of 18 in. or 20 in. extension? The lens I have is a 9" x 7 R.R., and will only copy to the same size as original. I once used a very small lens, which at about 10 inches extension of the camera would enlarge from a midget to a cabinet, but I forget what lens it was. Would a  $\frac{1}{2}$  plate wide angle do, and would it cover if stopped down, say 1-1 plate or 12 x 10?—CORVIST.

If you only want to enlarge midgets, a lens of three or three and a half inches focus will do. With one of three inches focus you will be able to enlarge to five diameters in your camera on any size plate it will take. Of course, you could lengthen the camera by fitting an extension cone, or tube, on the front. If you refer to page 953 of the Almanac you will see a table which shows the distance required for different degrees of enlargement, with different focus lenses.

**LENS QUERY.**—Will you please advise me as to most suitable lens at moderate cost for studio 25 ft. long (that is the total length). Lens is required for all-round cabinet work, full lengths, busts, etc. Just now I am using a 8 x  $6\frac{1}{4}$  "—, Petzval formula, back focus  $8\frac{1}{4}$  f/4. But it does not cover very well, even at f/8. Your advice will be esteemed.—LENS.

Any good cabinet lens (portrait) of from eleven to twelve inches focus will do what you require. As a lens of that focus requires a distance of about eighteen feet between sitter and camera you could employ it in your studio, without great inconvenience, even in taking full-length figures. For three-quarters and busts you could not have a better lens.

**MOUNTING, VIGNETTING.**—1. Would you give me the formulae for mounting bromide and "Japane" prints? I find that the edges come up when dry. I use the best starch of good thickness. There used to be trade mounters of photographs; they, I believe,

used French glue. Could you give me the quantities, and is it safe from fading? 2. How is the soft effect got in portraits with light draperies shaded off at the edges, but the shaded effect starting well into the picture, showing the draperies faintly through? Is it done in the camera or in front of the lens, and what material is used and at what distance from the lens? Not to be confused with the Russian vignette.—E. J. HASSOCK.

1. Starch paste is what is generally employed for the purpose. If it is used thick, and well rubbed round the edges of the prints, they will not come up when dry. Many of the French glues are acid, and for that reason are not suitable for mounting photographs. 2. It may be got by vignetting, placing the vignetting mask at a good distance from the frame. Most of the large dealers supply a vignetter that is fixed in front of the camera, which will shade off the figure at the lower portion in the negative.

**TRANSFERRING P.O.P.**—Please advise me how to transfer P.O.P. prints on glass and china.—S. M. T. (Newfoundland).

A method which has been advised is: "The print obtained, toned, and fixed in the usual way—care being taken to use no alum—is first soaked in cold water and then applied, face down, to the surface with which it is required to make contact. It is important that the surface should be clean and perfectly free from grease. Good contact is secured by squeezeing the print, which is then left to dry. After drying, hot water is run over the back of the print until the paper commences to peel off. A corner is then taken between the fingers, and the removal of the paper is effected carefully. The surface of the gelatine is sponged with a pad of cotton-wool dipped in hot water, and the transfer is allowed to dry in a place free from dust. The temperature of the water should be about 160deg. F." We should, however, recommend the carbon process in preference to the above.

**A POSTCARD TROUBLE.**—I should be glad of some advice, through your columns, on the following difficulty. I have toned some postcards with ferrocyanide and sodium sulphide. After this treatment the writing space will not take the ink properly; it absorbs it and spreads, although before treating it is quite satisfactory. It appears as if the alkali in the sulphide bath has broken down the sizing. Is it possible to treat the card so that this spreading of the ink will not take place? Perhaps coating with starch or gelatine would prove beneficial?—HYDROLYSE.

We have not heard of this trouble before. Possibly treatment with chrome alum or formalin before toning would preserve the sizing; if not, the only apparent remedy is to resize with starch or gelatine, as you suggest. This could be effected after toning, but we should apply a hardening bath to the image before resizing.

**IMPURE MOUNTS.**—Can you give me any idea as to whether the spots on the accompanying platino-matt prints are due to faulty manipulation, defective mounts or paper? These were toned only last Tuesday with several others, which are apparently all right. Only those mounted on similar mounts to these show signs of spottiness! What would be the cost of chemical analysis to discover the cause of the decomposition? A reply in this week's "B.J." will oblige.—S. H. GREENWAY.

From what you say it seems evident that the mounts are at fault. We should cut up a mount and boil it in distilled water, and then test the water for hypo by adding, first, a drop of starch solution and then a little iodine solution drop by drop. If the first drop of iodine turns the solution blue there is no hypo present, but if the first few drops have no such effect the mount contains hypo. The quantity of iodine solution required to produce the blue colour will give you an idea of the degree of impurity of the mounts. The test can be made by yourself quite easily.

**METHYLATED ALCOHOL.**—There is no other way of obtaining methylated spirit without the admixture of mineral spirit than by obtaining an excise licence to purchase it. You seem to understand that matter, and we can tell you that no methylator would let you have a gallon or two "on the quiet."

**X. X. X.**—You have no ground for action. Your late employer cannot be compelled by law to give a reference. When an employer gives a late employee a reference he does it as an act of grace, and

not because the law compels him to do so. Yours, however, seem a somewhat hard case.

**PUZZLED.**—The cause of the tint on the whites of the vignettes seems to be that they have to be exposed to too strong a light while the free silver was being washed out before toning, or while they were being toned. One of the prints shows a decided mark where another one shielded it from light for a time.

**W. CONNOLLY.**—(1) Bevelled edge glasses for mounting photographs in optical contact with the glass are supplied by all the large dealers, such as Marion's, Houghtons, Fallowfield, and the like. (2) We must have fuller particulars before we can answer this question. So far as we can judge, the material is not at fault.

**DISTILLED WATER.**—I often see it recommended to use distilled water in making up solutions, but it is difficult to get it about here. Where I am engaged in business there is a small steam engine constantly running and it would be an easy matter to fit a condenser to the exhaust pipe and so get a plentiful supply of what I suppose would be distilled water. Will you be good enough to say if this would do as well as that sold by the chemists?—STEAM.

What you would obtain would certainly be distilled water of a kind, but as the steam will have passed through the engine it will be largely charged with oily matter and thus the water will be far more impure than the general run of tap water.

**C. B.**—If the negative is varnished with a varnish that has shellac as its basis, as is most likely the case, the coating can be got off by soaking the plate in strong methylated spirit. If at the expiration of half an hour or so, it does not seem to be dissolving the solution may be assisted by gently rubbing the negative with a pledget of cotton wool. Should it then refuse to come off a little liquor ammonia must be added to the spirit, and after time the rubbing with the cotton wool should be repeated. After the varnish has all been got off, the plate should be rinsed two or three times with fresh spirit. You must keep in mind that all traces of the varnish must be got rid of before any attempt is made to intensify the negative, otherwise unequal intensification will result.

**SILVERING MIRROR.**—I have a reversing mirror that I bought, second hand, a few years ago, and I have recently tried to re-silver it according to the formula in the "Almanac," but, so far, it has been a failure. The silver seems to have deposited all right, but instead of being bright and polished, it has a yellowish brown colour. The deposited silver seems to be very firm on the glass, but of a bad colour. Can you kindly tell me where I have probably gone wrong?—T. (Liverpool.)

In silvering mirrors the temperature of the solutions, and that of the room in which the work is carried out, is a factor in the case. If the temperature is much below 65 deg. or 70 deg. Fahr. a satisfactory deposit is seldom obtained. It must be kept in mind that, however good the silver deposit may be, it will not be fit for use until it has been polished. This is done with a pledget of fine wash-leather and the finest jeweller's rouge. The mirror must be made thoroughly dry and warm before it is polished, otherwise the silver will be distributed. Have you tried polishing the silvered surfaces you have obtained? If not, we should advise you to do so and see the effect.

**\* \* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

Dr. Kenneth Mees and Mr. S. H. Wratten, as the result of examining photo-sensitive silver acetylide, have found that no latent image is formed. As no sub-salt appears theoretically possible, the observation supplies support of a negative kind to the sub-salt theory of the latent image. (Pages 827 and 831.)

The ingenious suggestion of using two fixed-focus cameras placed front to front for copying same size has been made by Mr. A. Lockett in a contemporary. (P. 826.)

The making of a single panoramic print from a series of negatives is a task which may frequently be an advantage to the technical photographer. Some practical notes appear on page 827.

The opportunities for portrait work away from the studio are the subject of a recent exhortation by an American writer. (P. 830.)

The use of the swelled-gelatine process in making matrices from which casts may be prepared is deserving of further attention by those working for the professional photographer, as it enables various articles of ornament to be produced. (P. 828.)

A spirituous alkaline solution, caustic potash in methylated spirit, is the best means of removing varnish from a negative, but some further precautions are necessary in order to leave the negative in condition for further treatment. (P. 825.)

An incident which creates a disquieting sensation in regard to photographic trade with the Near East is reported to us by a Berlin correspondent. (P. 829.)

A lengthy patent deals with the construction of self-developing roll-film cartridges. (P. 834.)

A curious kind of compliment is paid one of Mr. Arbuthnot's pictures in "Photograms of the Year," just published. (P. 837.)

## EX CATHEDRA.

### Spurious Goerz Lenses.

One of the most barefaced frauds which we can recollect to have come under our observation has recently been perpetrated, and as it probably represents others it is well that we should caution our readers, though we cannot imagine that there are many who will be taken in by so palpable an imposition. The fact is that at a Glasgow auction sale room a lens professing, according to the engraving on the mount, to be by the firm of C. P. Goerz, was offered for sale and purchased for 17s. 6d. When we say that the lens was marked as 12 x 10 Pantar anastigmat, which would cost new about £14, it is hardly possible to extend much sympathy to a buyer who further ignored the fact that the fraudulent vendor, in selecting a lens to pass off as a Goerz, had not even taken the trouble to remove the original designation of "Primus Rapid Rectilinear," nor to alter the markings of the diaphragm scale which registers only to the aperture of  $f/8$  whilst the lens elsewhere bears the spurious marking  $f/6.3$ . It was but some months ago that a case of spurious Goerz lenses transpired in Glasgow, the guilty person in regard to which was, we have heard, sentenced to imprisonment on another charge. Whether the recent incident does or does not indicate the return of this inept malefactor to active life, there is evidently still reason to caution the ignorant as to the spurious objectives which may come their way.

### Removing Shellac Varnish from Negatives.

A correspondent last week wanted to know how to prepare a varnished negative for intensification. Unfortunately this is not a very easy matter—for various reasons. In the first place if we attempt to remove the varnish by soaking in spirit alone the removal must be quite complete before any water is applied to the film, otherwise shellac will be precipitated in the gelatine the moment the water touches the surface. A solution of shellac in alcohol is quickly precipitated by water, but if ammonia with a strong caustic alkali is present the precipitation does not take place. Shellac is soluble in ammonia solution as well as in alcohol, and though the solid lac dissolves slowly in either liquid alone, a mixture of the two is a powerful and rapid solvent. This fact, coupled with the one that water will not cause the lac to precipitate from the ammoniacal solution, renders it advisable to always use an alkaline spirit solvent. A very effective solvent is a solution made by dissolving one ounce of caustic potash in ten ounces of spirit. A plate may be soaked in this until the varnish has apparently all gone. After this a second bath of the same solvent can be applied for a few minutes and then the plate can safely be washed under the tap. Cotton wool should be used to assist in the process of removing the varnish, and it must not be forgotten that

all traces of alkali must be completely washed out before any attempt is made to intensify. If mercurial intensification is to be employed perhaps a mixture of alcohol and ammonia is safest, as the ammonia is more readily got rid of. The solvent effect of ammonia on shellac is sometimes made use of to produce a cold drying varnish. An alcoholic solution of shellac dried without heat leaves a dull surface, because the water that is always present in the alcohol evaporates so slowly that at the last there is an excess that precipitates the lac. If a little ammonia is added to the alcoholic solution this keeps the lac in solution until the last moment, and so a bright, clear varnish is produced. In the ordinary way we dry by heat, and this fuses the lac and gives a very hard film that it is often difficult to remove. In fact, we have known cases in which the complete removal of the varnish seemed to be almost impossible. After a prolonged washing and soaking it is generally possible to tell by inspection whether intensification can safely be attempted, but mishaps are not uncommon excepting when the worker is exceptionally careful to run no risks.

#### An Exhibition in Berlin.

Within recent years there has been an ever-increasing number of exhibitions for photographic materials held throughout Germany. One constantly hears manufacturers complain that the German photographic industry is, as they express it, "exhibition tired." In spite of that, these exhibitions flourish, and the manufacturers must find some benefits from them since they patronise them so well. Certainly English manufacturers who wish to introduce their goods on the Continent have no ground for complaint, as these exhibitions afford them every opportunity for doing so. From December 19, 1908, until January 3, 1909, an exhibition is to be held in the Zoological Garden Exhibition Buildings, Berlin, for scientific appliances. It is to include a photographic section, special attention being devoted to cinematograph apparatus and the various branches relating to it. There is also to be a department devoted to appliances used in synchronical photography.

#### Enlarging with Two Cameras.

In the "Photographic Monthly" Mr. A. Lockett points out that enlargements can very easily be made with the aid of two fixed-focus hand-cameras of different sizes. Suppose, for example, we have a Brownie, or similar small camera, and also a quarter-plate magazine camera. If we put the negative in the small camera—of course leaving the back open so that light can be transmitted through the negative—and then place the two cameras face to face with their

lenses in line, an enlarged image will be formed on ground glass of the larger camera, and we can then produce either a quarter-plate transparency or a quarter-plate size bromide enlargement with the greatest ease. Of course, if perfect focus is to be secured, each camera must be adjusted exactly for infinity, and it is advisable to make sure of this before attempting to enlarge. Light then emerges from the lens of the front camera as parallel beams, which are received by the second lens and caused to converge to its principal focal plane. Any two cameras may be used in this way; the box fixed form is not essential, and it is, indeed, somewhat of a convenience if one camera is of the focussing variety. One great advantage of the method is the ease with which full-size copies can be produced with two cameras of equal size. Practically the two lenses act as one lens of extremely short focus; thus, two five-inch lenses working together as an objective of about 2½ inches focal length, which is the reason why full-size copies can be produced in an apparatus with a total length of not much over 10 inches.

#### Steel Mirrors.

In an article on "A One-Exposure Three-Colour Camera" in "The Photographic Journal," Sir William Abney advocates the use of steel mirrors on the grounds that the metal is easy to work and rigid and not difficult to polish. A thin coating of collodion varnish protects the surface from damp. Such a mirror reflects only about 60 per cent. of the incident light, and this reduction might be serious in some cases, but all the same steel mirrors might be very serviceable for many purposes in which a surface-reflecting mirror is essential. The ideal mirror is, of course, a totally reflecting prism, but this is both expensive and heavy. On a score of permanence the metal mirror of Kahlbaum is excellent in every way as it is also optically, but is, of course, more costly than a steel mirror. As a rule when surface-reflecting mirrors are required we have to fall back on surface silvered glass which too often is very unsatisfactory. Many mirrors of this kind are very transparent, and transmit more light than they reflect. A really good specimen is not easily obtained, and when it is available it is very readily damaged.

#### Silver Acetylide.

The short paper which we reprint on another page, by Dr. Mees and Mr. S. W. W. in "The Photographic Journal," describes a very interesting and suggestive experiment with a silver acetylide emulsion, from which it appears that while light produces a visible image yet it does not form a latent image.

## THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1909.

Edited by GEORGE E. BROWN, F.I.C.

The forty-eighth annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published on December 1. This year's ALMANAC reached a total of over 1,000 pages, and the entire edition of 25,000 copies was sold out immediately. Of no other photographic book ever issued can two such unique facts be recorded. The edition for 1909 will also consist of 25,000 copies.

The editorial article will deal very completely with the important subject of

#### REFLEX CAMERAS,

and the systematic review of the work of the year under the title "Epitome of Progress" will be a strong feature of the volume.

The lines followed in the previous editions of the

ALMANAC will be maintained in general, but in a number of particulars the arrangement of the volume for 1909 will be modified to make it more than ever the book of universal photographic reference.

The ALMANAC for 1909 will appeal to photographers the world over as a daily reference guide in practical work. The standard matter and formulæ will be revised and added to where necessary, and, wherever practicable, new features of an informative nature will be added.

NOTICE—IMPORTANT.—Our publishers ask us to inform agents that it is advisable to place their orders for copies immediately, as considerably over half the issue is already booked, and a second edition will not be printed.

insusceptible to development. Theoretically it appears impossible that a subsalt of silver acetylide can exist, therefore we have here a case in which the absence of subsalt coincides with the impossibility of forming a latent image, a fact which may appear to afford a certain amount of negative support to the subsalt theory of the latent image. Then again the coincidence of a printed out blackened image with the absence of a latent image may seem to suggest that such images are generally of different natures. Possibly they are, but, of course, the experiments really prove nothing with regard to the action of light on silver bromide emulsions, for the very slightly known acetylide compound may have essentially different characteristics from a haloid salt. Though the writers almost seem inclined to apologise for publishing an experiment that has led only to negative conclusions, it appears to us to be one that was well worth carrying out, and that is also well worth remembering.

### Current Art.

The autumn shows of paintings give quite different notions of what work is being done amongst picture-painters. At the Institute one is struck by a sudden revival of the prouder days of old; at the Royal Society of British Artists one sees a retrogression towards the low level of the near past. It is a pity that the members do not more faithfully follow their president's lead, for Alfred East, A.R.A., dignifies the gallery with some majestic work. His "Wings of the Morning" is a notable landscape, with fine ideas and fine observation; it depicts a corn-field in the first grey light of dawn, before the colour has come into the sky. Overhead large, heavy clouds are scudding before the breeze, and they suggest the flight of great wings. D. Murray Smith shows several of his mannered but entirely pleasing landscapes. A. C. Gould's "Dunster Castle" and a fine portrait by Laszlo are exceptional works among much that is very ordinary, and similarly we must refer to G. G. Symonds' "Charlemont River in Winter," and A. Talmage's earnest and beautiful "Moonlit River"; F. Swinstead's two pastel subjects are as good, but not better than his previous works in this medium, which he uses with such facility. As a whole, however, the show is disappointing. In the Institute galleries one's spirits mount. The lighter, more cheerful rooms, and the importance of the works, and the goodly sprinkling of high reputations represented give us great hope of this somewhat unfortunate society. The finest things are J. Olsson's dream of opal colour, "The Afternoon Sun," an exquisite sea-piece; Niels M. Lund's "Glen Dochart," an amazingly strong painting of a burn roaring over the rocks; H. Van der Weyden's "Moonrise" and "Ram-parts," and Robt. Little's "Carrara Landscape." But there are a score of good things worthy of mention, such as G. Wetherbee's "Young Theseus," a Talmage, a Shannon, a Loudan, and others, for which we have no space. But we must congratulate the Institute upon having made a serious and successful effort to retrieve lost ground in the matter of reputation, and we can recommend the exhibition as an unusually good shillingsworth in the matter of pictures.

**Pentathionic Acid.** A short paper on this compound, by M. J. J. P. Valetton, in the "Recueil des Travaux Chimiques" (1908, p. 149), is of interest in view of the goldless toning bath of MM. Lumière, by whom its properties have been ascribed to the presence of pentathionic acid. M. Valetton has examined the behaviour of the solution of the acid towards a number of agents, such as caustic alkalies, ammonia, ammoniacal solution of silver nitrate, and ammonia cyanide of mercury, and has found that in every instance precisely similar results were

obtained when employing a colloidal solution of sulphur in place of pentathionic acid. He prepared his colloidal solution of sulphur by the modified use of the well-known "Wackenroder's Liquid," prepared by the customary method of leading a stream of hydrogen sulphide into a solution of sulphurous acid. He, however, precipitated the colloidal sulphur with common salt, dissolved it afresh in pure water, and thus obtained, after three or four precipitations, a solution which was quite natural to litmus. M. Valetton therefore casts doubt on the existence of pentathionic acid in solution, for the identification of which in an aqueous medium there is, he shows, at present no reagent.

### Photography in Bavaria.

The British consular report on the trade of Bavaria for 1907 and part of 1908, which has just been issued by the Foreign Office, states that the Munich Photographic School, founded in 1900, is now frequented by about 240 pupils instructed by fourteen teachers, and the premises will have to be enlarged. The art of photography is taught at present in twenty-two German universities and polytechnic high schools. With regard to photographic postcards the United Kingdom is considered not to be so good a customer as formerly for these articles on account of the reduced British prices. A Munich firm sought permission to import British postcards, to treat them for photographic purposes, and then to re-export them to the United Kingdom free of all duty. The Bavarian customs held that this might be conceded as no damage was thereby caused to other home industries. In consequence of heavy Russian tariffs, financial obstacles in Italy, and better labour conditions in Austria-Hungary, the Bavarian exports of photographic printing blocks to these countries have ceased.

### WIDE-ANGLE VIEWS WITH ORDINARY APPARATUS.

THE professional photographer who is very frequently called upon to carry out work which really requires apparatus costing more than the price of his labour justifies, is sometimes required to produce a photograph of large size of, say, a wharf or a factory, that must include the whole of the subject. This may sometimes mean an angle of 100 deg. or more, yet the distance the photographer can get back may not permit of that being done with any lens in his possession. Still, for business purposes, particularly in the case of large factories or the like, when the picture is to be used for advertising purposes, such a wide angle becomes imperative. Under these circumstances the question is whether the order should be declined or not. If the picture is taken in sections and joined together afterwards it is often objected to by the customer as not being satisfactory, but that is usually because the work was not so skilfully done as it might be—the pictures do not match in size, colour, or in perspective. However, by the system presently to be described, a little care will ensure this difficulty being overcome.

Let us suppose that the picture, to include all that is wanted, has to be, say, eleven inches by twenty-eight or thirty inches, and that the only camera available is an ordinary 12 x 10. In such a case we shall require quite four different negatives in order to get the most satisfactory result. The best lens to employ for the work is undoubtedly an anastigmat, or next to that a good R.R. that will cover the plate well to the corners with even illumination. For this a moderately small stop may be found necessary, even with a 12 x 10 lens. The camera should be placed opposite about the centre of the subject, and the tripod be very firmly planted, for it must be kept

in mind that on no account must it be moved from its position until the whole of the negatives have been secured. The camera must be perfectly levelled. That is imperative, otherwise the different negatives will not match properly. To ensure accurate levelling a spirit level must be employed. The first negative, which should be the centre one, is then taken and the amount of subject it includes is marked on the ground glass with strips of gum paper. The camera is then rotated either right or left by loosening the camera screw for the next negative. In arranging for this the camera must be rotated only so far that the second negative includes about an inch or an inch and a-half of the subject included in the first. This second negative is taken in the same way, also including some of the previous one, and so on with the others, as many as may be necessary to complete the picture. The object of having a certain overlapping of the subject in the different negatives is to obtain margins in the finished pictures that are well defined and equally illuminated, otherwise the joins, however neatly made, will be very palpable. For this reason it is often desirable to take, say, four negatives when perhaps three could possibly be made to include all that is required in the picture, more especially if a R.R. be used for the work, for even with the best of them there is a certain falling off in the illumination at the corners of the negative, but this will be cut away in the mounting. The little additional trouble, when one is about it, is well repaid by taking an extra negative or two when excellence in the result is the chief consideration.

In the development of the negatives care must be taken to make them all of equal density, otherwise it will be next to impossible to obtain uniformity in the prints. It goes without saying that unless the negatives are even the finished picture will not be satisfactory, either for framing or for copying for reproduction. In printing the precaution should be taken to cut the different pieces of the paper in the same direction from the sheets, because paper expands when it is wetted, and more so in one direction than it does in the other. It is scarcely necessary to say that all the prints should be printed to the same depth and toned to exactly the same colour.

Satisfactory prints having been obtained it now remains to trim and mount them, and that requires some care or the result will not be satisfactory. The best way of doing this part of the work is to take a sheet of glass somewhat larger than the finished picture will be. The centre section is then placed (untrimmed) in position on the glass and secured there with a few touches of thick india-rubber solution which will hold it securely. The next section—either right or left—is then adjusted in its position and secured in the same way. The overlapping portions in each section enable this to be done with the greatest accuracy. When all are fixed to the glass the prints are trimmed top and bottom by placing a straight edge along them, and, with a knife, cutting through the whole length at one time. The ends are then trimmed off in the same way. What now remains to be done is to trim the junctions so that they match accurately. This is an easy matter, though it requires some little nicety. It is done as follows: With a sharp penknife cut through to the glass both the overlapping portions of the various sections with one clean cut. In making the cut through the subject part of the picture it should not be in a straight line, but taken round about some inconspicuous parts, say the edges of shadows, and the overlapping portions of the prints give ample scope for this being done. In this way the joins will be practically hidden as the junctures will accurately fit one in the other. The finally trimmed prints are then taken off the glass and any rubber that may be adhering to the backs lightly rubbed off with the ball of the finger or a piece of india-rubber.

All that now remains to be done is to attach the print to the mount, and this is best done with thick starch paste. They should be mounted dry, as wetting them would cause expansion of the paper, and, moreover, the latter might become stretched in getting them into position. The dry-mounting (shellac) process is, of course, specially fitted for this part of the work. As an aid in securing accuracy on the mount it is a good plan to run a line along the latter to serve as a guide to the base line of the picture. If the above details be followed a satisfactory picture, including a very wide angle, can be produced that will be in good panoramic perspective, and, in the different prints with which it is built up are all of the same depth and tone, will appear as if it were made from a single negative.

### PHOTOGRAPHS IN RELIEF.

THERE is an application of photography that seems to be but little known or understood by photographers, though in some instances it might be turned to profitable account by professionals, and also be of interest to some amateurs. We allude to the production of gelatine reliefs from which casts can be taken in different materials—plaster of Paris and others, for example. In the Woodburytype process the finished print is merely a cast in pigmented gelatine of a gelatine relief from which a metal mould has been obtained. Some correspondents have at times asked how these are made, while others have detailed the difficulty they have met with in getting sufficient relief. It may be explained that a carbon print is in reality a relief in pigmented gelatine, and that is easily seen if a print be examined while it is still wet after development, and the relief will be more marked in it is made from a strong and vigorous negative than if it were made from a thin and feeble one. In the case of the carbon print, and also in that of the Woodbury gelatine relief, it is the portions unaltered by light which are dissolved away to produce the relief.

There is, however, another way of obtaining a gelatine relief in which the gelatine is not dissolved, yet a very high degree of relief is obtainable, even higher than in the method just referred to. This is by what is known as the swelled gelatine process, which is used in some methods of producing typographic blocks, though not so much now, perhaps, as it was some few years ago, since it has very generally been superseded by the present day process block. Everyone is aware that when gelatine is soaked in cold water it swells considerably in size as it absorbs the water. It is, perhaps, not equally well known that if the gelatine contains a bichromate salt and has been exposed to light, its character in this respect is entirely altered; it no longer swells up, however long it is soaked—that is if the exposure has been somewhat prolonged. In view of this it will be obvious to most persons that if a bichromated film be exposed under a positive, and then soaked in cold water, it will swell in proportion, as it has been protected by the various portions of the negative. The highest lights will swell up to high relief, whilst the deepest shadows will be unaffected, and as a result we get a picture in more or less relief with perfect gradation. From such a relief cast can be made in plaster of Paris or other plaster material. Having obtained the plaster cast, other casts in turn can be made from it in such materials as wax, stearine, spermaceti, and the like, and by impregnating the plaster cast with wax or stearine, electrotypes may be made from it. In this way we can reproduce photographs in a great variety of materials. It may be as well to explain here that when a carbon print, or a Woodbury relief, is developed, it is the portions unacted upon by light

which are dissolved whilst the shadows are in relief, you are sure of what you process it is just the reverse; it is the lights that swell up in the cold water and form the relief, while the shadows appear in intaglio.

In selecting a gelatine for the present work, Nelson's No. 1 sheet will be about as suitable as any. A good proportion to use is one part to three and a-half or four of water. The gelatine is dissolved in the usual way by first soaking it in cold water and then dissolving by heat. A cleansed glass plate is then warmed and placed on a levelling stand, and the gelatine poured on in sufficient quantity to produce, when dry, a film about the thickness of an ordinary thin business card. It is then allowed to dry, which will take some time, according to the state of the atmosphere. Under some conditions it may take two or three days, but the precise time is of little moment. Of course, the bichromate can be added to the gelatine solution, but in that case the drying must be done much more quickly, otherwise the film will become insoluble and lose its property of absorbing water and swelling up. It is therefore preferable to dry the coating first and sensitise it afterwards. That is done by soaking the plate for three to four minutes in a four per cent. solution of bichromate of potash to which a few drops of liquor ammonia have been added. It will then be found to take less time to dry than if the bichromate were added at first to the gelatine solution. It need not be said that the drying must be done in a yellow light and as quickly as possible.

In some methods of working, the insensitive film is stripped from the glass and sensitised afterwards, or the thin sheets of gelatine, as sold by those who supply lithographic material, may be employed. But on the whole it is, perhaps, best to use the film while on the glass, as when detached it is prone to swell considerably in a lateral direction. The sensitised film being perfectly dry, it is now exposed under the negative for the necessary time, which, it is obvious, must depend upon the light. For our present purposes direct sunlight is preferable to diffused light, as sharper results are obtained. As a rough guide to the exposure, it may be said that it should be until the deepest shadows have become a decided brown colour, while the

high-lights remain of much the same tint as they before exposure. After exposure the plate is put into a tray of cold water, when the unaltered bichromate should freely dissolve out, which it will do if the plate has not been much over-exposed, or the film become insoluble in the drying. After soaking a while it will be seen that the image is swelling up to a relief which will go on increasing by longer soaking. Sometimes to get the highest possible relief several hours may be necessary—perhaps ten or twelve if the temperature is low. It may be as well to mention that some workers, on failing to obtain the expected relief, have surmised that the gelatine film was not thick enough; that, however, in eight cases out of ten is not the reason, for it has been due to lack of vigour in the negative. It is next to impossible to obtain high relief unless a very vigorous negative—one with a long range of tones beginning with clear glass for the shadows—be employed.

When full relief has been obtained, the water on the surface of the film is removed by gently dabbing it with a soft cloth or handkerchief. When it has been made as dry as possible in this way the surface is rubbed over, evenly, with a little olive oil on a pledget of cotton wool. The plate is then ready for taking a cast in plaster of Paris. The plaster for the purpose is that used by those who make plaster images, and not that sold at the oil-shops, and it should be freshly burnt. Some of it is mixed with water to about the consistence of thick cream. The plate having been placed on the levelling stand, some of it is poured on to the thickness of a quarter of an inch or so, a camel-hair brush being used to remove air bubbles if necessary. When this coating or plaster has fairly set, a further, and this time a thicker, coating is applied to the depth of three-quarters of an inch to an inch. This is then allowed to set and become thoroughly hard, when it can be removed by inserting the blade of a palette knife round the edges. We now have a plaster cast from which we can obtain others as required—which, of course, will be a reverse as regards intaglio and relief. If the dried plaster cast be soaked in water, for example, then just surface dried, and melted stearine, wax, and the like, be poured on, we get a relief in these materials from which electrotypes in copper can afterwards be obtained.

## THE IRONY OF TRADING WITH THE ORIENT.

(From a Berlin Correspondent.)

THAT trading with the Orient is not altogether smooth-sailing many manufacturers of photographic goods know to their cost. It is not altogether from the uncertainty of being paid for goods ordered in a land which the European Powers have been waiting for years to put on a sound commercial footing, only that with very limited success, and apart from the difficulty as being the Oriental to think commercially and to give an answer, there are the still greater difficulty of getting the goods sent into the customs house. It is true that in theory there is a fixed tariff on goods belonging to the various classes that are fixed by the authorities, but in reality there is neither law nor order in the practical working of these tariffs. Every customs officer seems to be more or less a law unto himself; many of them have to have their palms well greased before they will stir themselves to assist in the expedition of goods, otherwise the packages may lie rotting in the customs sheds for weeks, or it may be months. Consequently the whole scheme is reduced to what has aptly been termed a medley of official corruption and bribery. Some merchants assert that these customs officials receive no other pay than the bribes they receive from foreign traders.

Be that as it may, the following story, which has been narrated to me by an exporter of goods to Turkey, would certainly be difficult to beat in any country. To the outsider there may be a spice of humour in it, but to the manufacturer it has proved very costly. He had shipped a number of cases containing photographic plates and films to Constantinople to be forwarded by an agent there to numerous customers throughout the country. The goods arrived safely, and the agent was duly notified to clear them at the customs house. After waiting for some days on the pleasure of the autocratic officers, who only examine goods when they have nothing else to do, the agent grew tired of it, and left the place for half an hour in order to go and have some luncheon. For some reason or others the officers took it into their heads to examine the plates and films during his absence. On each box instructions were clearly printed, in Turkish as well as French, I believe, that the boxes were only to be opened in a dark-room, but the officials paid no heed to this. Most of them are in mortal terror of gunpowder or dynamite being smuggled into the country, and would not for anything trust their precious heads in a dark-room with any foreign goods. Instead, they set to work in the brilliantly

shed, and when the agent returned he found to his horror that they had completed their task, and had arranged the plates carefully in long rows underneath some windows through which the sun was shining; this, by the way, with the intention of examining them more closely! Two officers were greatly tickled with the long spools of films, and were amusing themselves twisting them into all manner of comical shapes. In short, the

whole, what now remains to be done is ruined. To remonstrance I mourn, and this is best. Unfortunately for the manufacturer, sent the goods there is no possible chance of his ever being recompensed for the very serious loss which this instance of official stupidity has caused him. It is incidents such as this which discourage the trader in the Near East.

## OUTSIDE TRADE.

A Paper in "Wilson's Photographic Magazine."

If you haven't any, there is only one place to put the blame. There is always an outside trade for every business. If the man who runs the business doesn't get it, some other fellow will. These things being so, isn't it up to you, who naturally want to make all the money you can, to go after a little outside business?

Let it be understood right from the start that I am not attempting to tell you that you should try to cabbage the commercial trade from your commercial competitor, unless you are strong on that sort of work. But there is a great deal of trade belonging to you, and not to him, which he gets because you don't know enough to make it known that you want it. A commercial photographer, whose business it is to make landscapes and buildings and machinery and pet dogs and newspaper pictures, and a few other varieties, is not going to turn down an opportunity to make a portrait; but some such portraits, made under what are at best poor portrait conditions, are sights for the gods who oversee the mistakes of mankind.

If you know how to make a portrait under your light, you should know how to make one elsewhere. It isn't at all a safe gamble that you do, but if you know the principles, as well as the practice, of portrait lighting and making you will succeed as well in the home as in the studio, albeit with more trouble.

Now, suppose you try advertising the fact that you make portraits at home. Try something like this:—

*Let the Studio Come to You.*

If you cannot come to 999, Main Street to be photographed, I will bring the studio to your home.

I can make you a "home portrait" or I can make you a portrait in your home that is in every way the same as my gallery work.

SMITH, Photographer.

Put it in the paper. Put it in several times—the announcement, not the same wording—and see if you don't get plenty of replies. There are old people, and bedridden people, and sick people, and children and babies, and lazy people, and rich people, and people who want something new, and people who want to talk about something different! There are a lot of home portraitists travelling around the country and getting good prices for good work, and I don't see why they have to be out-of-town people to get the trade of your town!

Here is another card, just by way of suggestion:—

*Your Picture in Your Home!*

You cannot bring your home to my gallery, but I can bring the essentials of my gallery to your home. Your portrait in the surroundings your friends know is something they will cherish.

The price is not high—ask me.

SMITH, Photographer.

Now agree with me, for the sake of argument, that you have orders for home work. How are you going to go about it? To transport your heavy screens and camera to a house is absurd. You have got to have some special rig to carry. Speaking from experience, I can assure you—and the best and biggest of home-portrait men will uphold the statement—you don't need half the things you will think you want.

You must have a camera and a lens.

Make it a light view camera, your portrait lens, and shutter. You must have a background.

You will have to have it, because some people won't want a home background; but because you won't need it all the time it is foolish to carry a lot, and heavy ones at that. Get a piece of dark red and light grey stuff, have them sewed back to back, put hooks on one edge, get some picture wire and two bradaws, and you are equipped. Roll it, don't fold it. You have thus two portable backgrounds, hooks to hang it upon wire, and bradaws to stick in the top of door frames and window frames, where the hole won't show, and to which you attach the wire.

You will want a reflector. I suppose nothing less than a wire ring and stand will do you; but if you can manage with it—as many a man does—a collapsible frame of light wood and a small piece of sheeting, the whole to be supported on a chair, is all that you need.

Finally, a small hammer, some tiny tacks and plenty of cheesecloth, and you are equipped to turn any room into a studio. If you cannot learn to so modify a window light with cheesecloth and reflector that you are enabled to make a first-class lighting, you had better keep out of the business; but just remember this, lots of men do it, and what others can do and have done you should be able to do also.

Because you will find people less critical of home work than gallery work is the poorest excuse in the world for doing work you would not let out of your gallery. The very amateurish amateur has set his ineradicable stamp on "home portraits," and your average customer will expect a soot and whitewash portrait, with ink for the shadow side, and be so pleasantly disappointed when she doesn't get it that she will overlook other shortcomings. But that is no excuse for making them, and you want to remember that there are others to see that picture, and critical others at that.

I should strongly advise your study of a book on composition. You have simply got to have some knowledge of line and composition and balance if you are going to make a success of making portraits with a background of reality, instead of the Stygian blackness or smoky cloudiness which your studio background allows you to use to hide possible errors of composition. Your patron may not know a plane from a pipe-stem, or most else at all the difference between a well-balanced picture and one that is toppling over into an abyss—may not know twell upjines lead and carry, or that there is a way into and a warious of any picture which is properly made; but some one with well judgment is going to know, even if they cannot put a maffed to it, when your picture is incorrect, and so you will snass or in the end.

You will find, of home portraits, the easiest to make are those which require but the head and shoulders. Unless you are a double dyed-in-the-wool, a yard wide, and warranted fast-colour home-portraitist, you want to watch with an eagle eye lest you attempt to make a head and shoulders with a "home" background. For that way lies the easy road to failure. It takes a pretty level head and a pretty good artist to put a large head and shoulders against anything but a plain and innocuous

background, and you are sure of what you are doing, plain backgrounds it is not meant that must show no design. One of the most pictures I ever remember seeing, made by an angel-faced child, by Pierce, of Boston, which an old artist, with a subdued pattern, was used as background. But here, again, is a pitfall. Beware of it! pattern in a background must never intrude—it must tone be a part—not stand out and seem to be that plane of the face and shoulders are a part.

The most effective home portraits are those pitched in a low—this does not mean a small range of deep shadows, where contrast is small. I cannot pretend to state why these pictures enjoy so much popularity, unless it is that one naturally seeks the opposite from much suffering at the hands of the amateur beginner and his steep mountains of contrast.

In portraits in the home, with the home background, watch carefully for the obtrusive background. You are not making a picture of a bookcase, of a desk, or a sideboard, or a chair, or a mantelpiece, or a fireplace. You are making a portrait of a person, and you are going to suggest their location and habitation, not shout it from the picture. You will have to learn something of the use of stops in separating planes, and learn that there is a degree of indistinctness which is pleasing, and a further degree which is inadmissible, and govern your lens opening accordingly.

I would warn you against the too conventional pose. Milady, reading a magazine by a lamp, which you "artistically" light in the retoucher's room, may be a masterpiece, but it is much more apt to give a real artist a pain. Grandpa dreaming over an open fire, made with a newspaper and frantic adjurations on our part to "sit very still—don't move—through in a minute," may please the bromine person, but will set you for ever beyond the pale of the truly elect. I would suggest your standing in a reverent contemplation before—well, Whistler's "Portrait of his Mother," for an understanding of what simplicity may mean a picture in the home.

Now there is the question of price. It seems to me that should do one of two things were I attempting to work up such a trade. I should either charge a high price for the single picture and a reasonable one for the dozen, or I should charge so high a price, single or by the dozen, that people would not want very many. Both courses have something to recommend them, and it largely depends on the kind of town and class of trade you have. On the whole, I incline to a reasonable charge by the dozen or half-dozen, but a stiff price for the single picture. There is too little profit in the single picture at anything less than a stiff price to make it worth while. On the other hand, if people want a single unique picture, as they have been known to do, the stiff price goes without question.

But making a dozen at home at but a small increase over gallery charges gives you a beautiful chance to advertise that your price is not high; and, if you have the time, or can hire a good man to do such work, you can well afford to make three or four "sittings" at home in a day—or in a week—at a price not greater than one-third more than your regular gallery price for the same size picture—always providing that your gallery does a reasonably high class of trade. If you are making cabinets at \$10 the dozen, you can make them at home for \$12.50—certainly for \$15. If you get \$18 in the studio for an 8 x 10 you should be able to make it \$24 to \$30 in the home. Many home portraitists would hoot at such prices—they get from \$5 to \$10 per single picture, and it is exactly in this terrific price that your opportunity lies. They could hardly do it for less and live—doing that exclusively. With you it is, as it were, a side line, and gives you an opportunity for extra money which should be all to the good, even if done at a moderate profit—a profit you could not live upon were it your sole source of income.

You are facing your busiest season. Immediately after it comes the dull times. If you can work in some of this home portraiture for the Christmas trade you will have a start which should be able to develop in the days when orders inside are slack.

C. H. CLAUDY.

## SILVER ACETYLIDE EMULSION.

(A communication to the Royal Photographic Society.)

It is well known that if acetylene gas be bubbled through an ammoniacal solution of silver nitrate, precipitate of silver acetylide is obtained. This substance is chiefly distinguished for the violence with which it explodes when heated. It was found, on preparing a quantity of the precipitate, that it is very light-sensitive, darkening more rapidly in daylight, when suspended in water, than any other silver compound with which we are acquainted. This light-sensitiveness suggested to us that it would be of interest to investigate the properties of an emulsion formed from silver acetylide for the formation of a "latent image."

The "chemical" nature of the "latent image" of the ordinary platino-bromide emulsion appears to us to be substantiated by the fact that that image can be removed by ordinary chemical oxidisers as bichromates.

There are three chief "chemical" theories as to the nature of the "latent image"—

- That the "latent image" consists of a subsalt of silver.
- That the "latent image" consists of metallic silver.
- That the "latent image" consists of a colloidal lake of metallic silver with unaltered silver salt.

From the investigations of Carey-Lea and Lüppo-Cramer there appears to be little doubt that the visual photo-image formed on exposure of an emulsion to light is of the nature indicated in (c).

It was shown by S. E. Sheppard that it would be improbable that the "latent image" consisted of ordinary metallic silver, because oxidisers of a sufficient potential to bleach a developed plate were incapable of destroying the "latent image."

We are therefore left with the possibilities of a subsalt of silver

or of a colloidal lake of metallic silver similar to the "photo salts."

Now from the nature of silver acetylide and its great instability it is improbable that any sub-salt could exist, so that if silver acetylide emulsions could be formed which should give "latent images," those images would probably belong to classes (b) or (c).

On the other hand, it is, of course, possible that lakes which would be easily formed with other salts of silver could not be obtained with silver acetylide.

It may be well here to define what we mean by the term "latent image." We may define a "latent image" as a condition caused by exposure to light, which will increase the rate of reduction of the silver salt by a reducer. That is, if on "development" a difference between the unexposed and exposed portions of the emulsion is perceived, we may consider that a "latent image" has been formed by the exposure. Thus silver chromate emulsion forms a "latent image" which is developable by neutral ferrous sulphate solutions, while silver erythrosinate gives one developable by the ordinary alkaline reducing agents.

The silver acetylide emulsion was prepared by precipitating silver nitrate solutions with ammonia and adding further ammonia until the precipitate just redissolved. Five per cent. of soft gelatine was then added to the solution, and the solution placed in a gas absorption bulb, through which acetylene was passed in the dark.

A heavy crust of the salt was formed on the surface, but a fine grained emulsion was also formed (probably as the acetylene dissolved).

The crust was removed and the emulsion coated on plates which were then washed for twenty minutes in running water and dried.

other emulsion after precipitation was cooked at 70deg. C., and plates coated every ten minutes up to forty minutes.

All these plates gave the same result. They were extremely sensitive to light, showing a blackening in about one-tenth of the time in which a change is first absorbed on gelatino-chloride paper. But however much or little they were exposed, they showed no difference whatever between the exposed or unexposed portions on development.

Alkaline reducers blackened the whole plate uniformly, while neutral or acid ones either blackened it uniformly or produced no change.

We therefore conclude that silver acetylide does not give a "latent image." Though our conclusions are thus negative, they seemed to us of sufficient interest to be worthy of publication.

S. H. WRATTEN.

## A SPEED-TESTING DEVICE FOR PHOTOGRAPHIC SHUTTERS.

THE cut below represents a new and very ingenious device for testing the speed of shutters. The machine was designed by Mr. Fred Schmid, of the C. P. Goerz American Optical Company, and is in use at their New York factory. The essential parts of the device are: a hollow metal drum (D), perforated spirally by a series of 200 holes making exactly one complete revolution around the drum; a front board (FB) with a narrow slit (S) in it, equal in length to the distance from the first to the last hole of the spiral perforations and placed exactly at the same height as the axis of the drum; a mercury vapour lamp (L); a small electric motor (M) and such mechanical appliances as are necessary for revolving the metal drum at various required speeds.

The use of the apparatus is as follows: The lighted tube, supported

ing on the slit in the reproduction is an example. The single and double dots appearing in the reproduction are openings in the front board above the slit and facilitate the counting of the dots by marking groups of five and ten in the negative.

In making the exposure a special plate holder is used which permits of the same plate being used for a complete test of all speeds of the shutter. This is brought about by means of a device by which the plate is raised or lowered in the plate holder.

The length of exposure is figured out from the negative in the following manner: Knowing the speeds at which the shutter was set and the time value of each dot, derived from the speed of revolution of the drum, multiplying the value per dot by the number of dots gives the actual length of exposure. If the value of each

horizontally, is placed inside the drum, the drum is then revolved at a given speed which is ascertained by a striking bell mechanism (SB), giving one stroke for every five revolutions of the drum and thus permitting an accurate determination of the speed of rotation. The speeds, in practice, vary from three to eight revolutions per second and as the drum revolves each perforation therein appears in turn before the slot in the front board. To a spectator who is watching the operation the slit appears as a continuous row of light-dots blending finally into one line of light.

The shutter to be tested is attached to a camera, placed in the front of the apparatus, focussed on the slit, and with the drum revolving at a known speed and the shutter set for a given speed, an exposure is made. The photographic image which appears on the negative is a succession of dots of which the single white dot appear-

dot is determined at 1/1000 of a second and the shutter was set for 1/100 of a second ten dots would indicate the exposure to be 1/100 and the shutter to work accurately. However under same conditions should 20 dots appear in the negative the actual exposure would be 1/50th of a second and show the shutter working slower than marked.

An important feature in regard to this device is that it is equally well adapted for testing focal plane shutters. This is due to the fact that the record is produced on a straight horizontal line and will thus be correctly exposed by the slit in the focal plane shutter.

The device was designed in order to insure the accuracy of the XL Sector shutter manufactured by this company, and it is by virtue of many tests made with this apparatus that they make the claim for their shutter that "you can rely on it perfectly."

**THE DANGER OF CINEMATOGRAF ENTERTAINMENTS.**—The Works Committee of West Ham have had under consideration the question of the use of shops and other unlicensed premises for cinematograph entertainments, and the danger likely to arise to the public in the event of a panic arising from fire or any other cause. They were advised that under the existing law such entertainments can be carried on without a music licence, and the Council have no control

over the buildings used, which, in the opinion of the superintendent of the Fire Brigade, are unsuitable for the purpose, and, in some instances, a source of danger to persons witnessing the entertainment. The Council have decided that the attention of the Home Secretary be called to the subject with a view to the promotion of legislation, placing all such entertainments under the notice of Councils as the licensing authorities.

## Exhibitions.

### HOVE CAMERA CLUB.

At the Hove Exhibition, which was held last week, the judge, Mr. Furley Lewis, awarded thirteen replicas of a statuette in art metal designed by Miss Mary E. Arthur, of the Brighton School of Art. The statuette is a female figure representing the "Genius of Light." Two go to Mr. Chater Lea, who, in addition to energetically carrying out the duties of exhibition hon. secretary, has sent in a number of exceedingly attractive works. The best effort among the club members, however, was attributed by the judge to V. E. Morris. For the second year in succession he was given the championship salver, the picture which has won him this prominence being a very difficult study of the cloister window in Chichester Cathedral. The sunlight effect is splendidly conveyed.

In the open class attention will inevitably be focussed upon Oscar Hardee's portrait of two Dutch fisherfolk. Councillor A. R. Sargeant, J.P., the president of the club, to whose exertions the members owe so much, has gained notice, his "Low Tide, Bosham," being honourably mentioned. The full list of awards is as follows:

#### OPEN CLASSES.

Class "A"—Prints (any subject).—Statuettes, "Summer," Mrs. G. A. Barton; "The Convent Well," John H. Gear, F.R.P.S.; "Lady with Lace Collar," R. Dührkoop; "Isabella en Jan Wilden," Oscar Hardee; two series, "Tawny Owl" and "Song Thrush," A. Taylor; Autochrome transparency, Captain W. Stomm; "The Darning Lesson," Aubrey Harris. Hon. mention, "The Spell," Mrs. E. Peake; "Oranges and Bananas," E. W. G. Burder; "Edinburgh Castle," Dan Dunlop; "The Imposition," G. C. Vachell; "Low Tide," A. R. Sargeant; "Crypt, Hereford," S. G. Kimber; "Grootte Kirke Edam," F. J. Phillips; "Shepherd and Flock," W. Chater Lea; "A City Church," B. C. Wickison; "The Abbey Stream," John H. Gear, F.R.P.S.; "A Matter of Opinion," B. Cox; "Snow in April," Miss A. B. Warburg; "The Harvest that is to Be," Oscar Hardee; "Col. Heathcote," G. C. Vachell; "Mother and Child," H. Hinz.

Class "B"—Lantern Slides.—Statuette, "Looking into Cloister, Chichester," V. E. Morris. Hon. mention, "Blue Tits," A. Taylor. Autochromes, P. D. Prior.

#### CLUB CLASSES.

Challenge Salver for best picture in Club Classes, presented by W. A. Hounsom, J.P.—"The Cloister Window, Chichester," V. E. Morris.

Class "C"—Prints (any subject).—Statuettes, "What shall we put next?" W. Chater Lea; "A Bend in the Lane," W. Chater Lea; "Cloister Window, Chichester," V. E. Morris. Hon. mention, "On the Sussex Ouse," E. Munt; "Mischief," F. R. Richardson; "An Old Street Corner," W. Chater Lea; "April, 1908," G. A. Hammond; "On the Arun," F. H. Rake.

Class "D"—Lantern Slides.—Statuette, "National Gallery," V. E. Morris. Hon. mention, "Street, Polperro," W. Bailey; "Canal, Gorincham," V. G. Young.

Class "E"—Novices.—Statuette, Miss E. M. Boynton. Hon. mention, G. A. Hammond.

### FORTHCOMING EXHIBITIONS.

October 27 to 31.—Heaton and District Camera Club. Secretary, George C. Urwin, 24, Tenth Avenue, Heaton, Newcastle-on-Tyne.

November 2 to 11.—Portsmouth Camera Club. Sec., F. J. Lawton, 20, Clarence Square, Gosport.

November 4 to 7.—Hackney Photographic Society. Secretary, Walter Selve, 70, Paragon Road, Hackney, N.E.

November 11 to 14.—Cambridge and District Photographic Club. Sec., T. J. Sowdon, Sunny Side, Guest Road, Cambridge.

November 20.—Redhill and District Camera Club. Entries close November 7. Sec., J. Paterson, Ness House, Redhill.

November 23 to 26.—Lancaster Photographic Society. Entries close November 14. Sec., J. Holt, 11, Fern Bank, Lancaster.

December, 1908, to January, 1909.—Kiew International Photographic.

Sec., S. T. Horovitz, Technical Society, Kreshtchatik, 10, Kiew, Russia.

1909.

January 6 to 27.—Northern Photographic (Manchester). Entries close December 11, 1908. Sec., S. L. Coulthurst, Broad Oak Road, Worsley, Manchester.

February 13 to March 13.—South London Photographic Society. Sec., H. Creighton Beckett, 44, Edith Road, Peckham, S.E.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for Patents have been received between October 12 and October 17:—

CAMERAS.—No. 21,609. Improvements in photographic cameras and camera fittings. Henry Major, 24, Sarholme Road, Forest Hill, London.

DARK-ROOM.—No. 21,684. Automatic folding and portable dark-room. Nicholas Vladimiroff, 61, Talbot Road, Bayswater, London.

CINEMATOGRAPHS.—No. 21,787. Improvements in apparatus for imparting a positive intermittent travelling motion to cinematograph films. James Williamson and Colin Martin Williamson, 11, Wilbury Villas, Hove, Brighton.

### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

COMPOSITE GLASS PLATES.—No. 13,733. 1906. The invention consists in a method of joining pieces of glass to each other for photographic and other purposes in such a way as to avoid unsightly joins. For this purpose thread, saturated with adhesive matter and preferably of loosely twisted structure, is wound round the edge of a straight-edged plate of glass—that is to say, a plate with edge surfaces perpendicular to the back and front surfaces; the said thread is pressed against the edge surface and the backing or supporting plate, and another plate of glass, similarly treated or without thread at the abutting surface, is placed adjacent the first plate, the abutting edges of the plates being pressed tightly together. This process is repeated until the requisite number of plates have been joined together. If the plates are of uniform size and shape a single thread may be wound round a series of plates placed edge to edge, and one row of plates may then be joined to another row, the latter having thread placed on the edge surface to which another row of plates is to be joined. The individual plates or series of plates are pressed together as tightly as possible, and a suitable implement may be used to press the thread against the edge surfaces and against the backing. The space intervening between the plates at the joints is only equal to the diameter of the thread, and the joints are, therefore, not unsightly, and do not represent an appreciable amount of lost space.

The hardening of the adhesive causes the individual plates to be joined tightly together and to the backing, so that the composite plate can be handled and treated like an ordinary homogeneous plate. The individual plates can, however, be separated from each other with comparative ease by detaching portions of the thread and then pulling it away from the plates; in order that this can be done the strength of the thread must, of course, be greater than that of the adhesive.

In addition to the advantages already referred to, namely those of improved appearance—for example, in the case of transparent glass pictures, and of greater efficiency in the case of photographic plates—the invention has the advantage that no adhesive penetrates between the surfaces of the individual glass plates and backing; this is important, since the presence of adhesive between the plates and backing renders it very difficult to detach the plates. H. J. Haddon, for the Rotaphot Gesellschaft für Photographische Industrie, Berlin.

FOREGROUND SHUTTER.—No. 23,020. 1907. The object of this invention is to provide a cheaply constructed shutter for photographic lenses whereby various exposures may be given of different parts

of a plate so that the sky and foreground will be exposed to the actinic action of the rays of light during different lengths of time so that clouds can be taken with landscape and an even negative be obtained under all conditions. Fig. 1 is a front elevation of

Fig. 1.

the shutter. Fig. 2 is a vertical section. Fig. 3 is a section on the line  $x-x$  of Fig. 2, and Fig. 4 is a front elevation, in part showing a modification.

The shutter comprises a suitable frame which may consist of two plates 1, preferably formed with a ledge 2, and a strengthening strip 3, and having a circular aperture 4 corresponding to the lens. At the back of the frame is a socket piece 5, which is hinged to the frame or to a strip 6 on the frame, as at 7, and affords means for adjusting the device on to the lens, there being a spring 8 to keep the socket in closed position. The hinge enables the frame to be folded back when focussing the lens. Suitable guides 9—preferably formed on the edges of a metal plate 10—on the outer face of the frame retain a reciprocating shutter 11 in which is a narrow slit 12 corresponding in length to the diameter of the aperture 4. A spring catch 13 secured on the frame at 14, and engaging a projection 15 on the shutter, holds it in such position that the slit is above the aperture in the frame. The catch can be released and the shutter be permitted to fall by means of the usually employed rubber bulb 16 and the expansible bulb 17. A cylinder

Fig. 2.

Fig. 3.

Fig. 4.

18 is secured to the frame adjacent the shutter, by bands 19 or other means, and is fitted with a piston 20, having a rod 21, which projects from it and is adjustably fastened to the projection 15 by a set-screw 22. The cylinder has a small perforation 23 at the bottom, and a slightly larger one 24 about midway its length.

When the shutter is released it will (together with the piston) fall rapidly until the perforation 24 is passed by the piston 20, and then more slowly to the bottom by reason of the air in the cylinder escaping through the lower and smaller perforation 23 only. The escape of the air, and, consequently, the speed of the shutter, can be regulated by alteration in the size of the perforations, and that may be effected by any suitable means, as, for instance, a ferrule 25 movable around the cylinder, having a perforation 26, and the perforation more or less covering the perforation 24 in the cylinder as the ferrule is turned. At the bottom of the cylinder is a disc or cap 27 having a perforation 28 arranged to operate in a similar manner by turning it round.

In an alternative construction, the piston-rod 21 may be carried up beyond the projection 15 on the shutter, be formed with a piston 29 at its upper end, and enter a cylinder 30 of smaller dimensions than the cylinder 18. The upper end of the cylinder is closed with the exception of a perforated nipple 31, to which the tube of the rubber bulb is attached. Air forced into the cylinder 30 causes the piston and rod to descend, carrying with them the projection 15, to which said rod is secured by the set-screw 22. The projection 15 is forced from beneath the curved part 32 of the spring, and the shutter, being then released, its action is the same as that described with reference to Fig. 1. Henry Arthur Byers, of Pe Ell, Lewis County, Washington State, U.S.A.

SELF-DEVELOPING ROLL FILM CARTRIDGES.—No. 21,692. 1907. The purpose of this invention is to provide the films with an improved form or system of packing that allows them to remain in their original wrapper, spool, case, or packing from the moment they leave the manufacturers' hands to the completion of the negatives—that is to say, the film package with its complete packing is loaded into or unloaded from the camera in daylight, is placed in the developing, fixing, and washing solutions in daylight, for which purpose the outer packing box may serve as the developing tank, and the finished negatives are finally removed from the packing in daylight, the packing being then thrown away.

In order, therefore, to carry this invention into effect, the first essential is that the layers of film whilst in their package shall be separated by a space of sufficient width to allow developing solution to pass between each layer and reach the sensitive face of each film. These spaces are termed "water spaces."

It is further necessary that these "water spaces" in the interior of the package shall communicate with the exterior by means of water vents formed in the enclosing wrapper, spool, case, or packing, and that such water vents shall be light-tight.

These water spaces between the films are filled up by a so-called "developing wrapper." This wrapper is made of absorbent material, with or without water-distributing channels, and lies between each layer of film, one side being in close contact with the sensitised face of the film. Its function is to prevent uneven development, it being so constructed that it distributes the liquid developer to the whole surface of the film in an even layer.

The introduction of water spaces between superimposed layers of rolled film is not new, for this principle obtains in the systems of developing tanks now used for developing and washing films, but in such systems the exposed film has to be wound off its flanged daylight spool, upon which it was already wound and packed for sale, the water spaces being then formed by winding the film on to a spool of large diameter, and placing between each layer of the coil a separator called a "developing apron," consisting of a sheet of celluloid having thickened edges of serrated rubber, or similar rubber strips at each side without the connecting celluloid sheet.

The introduction of water spaces between layers of flat film has also been proposed, and chemicals for developing and fixing have been applied to films and plates as in the patents of Thornton and another, 17,292 of 1899.

The standard form of daylight-loading roll film as ordinarily constructed comprises a light-tight carrier, consisting of a spool or bobbin with light-excluding discs at each end and suitable centres and keyways; a long strip of black paper or light-excluding wrapper coiled on the bobbin and fitting closely against and between the discs; and in this carrier is enclosed a strip of sensitive film, shorter than the wrapper, but attached at one end to the wrapper and rolled up in it. Numbers or other indicating marks are printed upon the back of the wrapper. Other forms comprise a film having an opaque coating attached to the back instead of a separate wrapper. Other forms, again, have neither opaque wrapper nor backing, but have opaque ends or extensions of the strip itself.

The standard form of daylight-loading flat film is known as a "film pack," and, as ordinarily constructed, comprises a series of flat films placed in a pile in the front compartment of a light-tight carrier, consisting of a shallow box; the box having an exposure opening cut in the front, and a spring pad or division plate inside the box, dividing it into two compartments. The films are placed between or are attached to leaves of opaque paper, having numbered extensions that form pull tabs by which the films may be

drawn from the front to the back compartment of the case, the manipulating tabs passing through a light-tight valve in one edge of the case. The front aperture is closed by the manufacturer by means of a shutter or cover of opaque leaves having its own pull tab. In improved forms the film, the opaque backing, and the pull tab are all made in one sheet or piece. Examples of these film backs and their improvements are shown in patents Nos. 4,955 of 1898, 11,033 of 1906, 11,884 of 1906, 12,003 of 1906, and 21,189 of 1906. It is to either of these standard forms that the invention is applied.

The improved film package of daylight-loading and daylight-developing films comprises, as a whole, the following features:—

(A) A series of superimposed layers of sensitized film A.

(B) A light-tight carrier for same, comprising either a bobbin B and wrapper *b* for roll films, or a case C with wrappers for flat films.

(C) Water vents in the wall of such light-tight carrier effecting communication between the interior water spaces *a* and the exterior.

(D) A series of water spaces *a* inside the packet—one between each layer of film A.

(E) Means for separating the films and maintaining these water spaces, and a water-conducting developing wrapper D, placed in each water space.

(F) A light-obstructing layer *b* between each film layer, formed either on the back of the film itself, or as a separate interposed sheet or layer.

(G) Numbers or other indicating marks, denoting the numbers and position of each exposure section of the series.

To these features may be added, in order to make the film package more complete and convenient:—

(H) A developer F, or developer and fixer G, consisting of chemicals in a dry form, soluble when the package is placed in water, such chemicals being applied either to the back of the film or to the opaque layer, or to the developing wrapper, or to the light-tight carrier, or to the enclosing packing case or tank.

(J) A water-tight air-tight packing case M, to enclose the light-proof film package and form the tank, in which it may be developed, fixed, washed, and stored or mailed.

The series of layers of film A are made in the ordinary way, and the light-tight carrier holding them (the spool bobbin B or the case C) is of ordinary construction, provided with suitable water vents. The water vents are formed as follows:—For roll films there is a pool or bobbin having a central core either of wood, with a central threading slot, or of a hollow tube or tubes, as used in Patent No. 17,737, of 1899. The end discs are of the usual diameter, the pool overall being of the standard dimensions, so that it will fit existing cameras.

The end discs, however, instead of being made of the usual single plate of metal (which would be useless, because it would prevent water reaching the film) are made to allow water to enter and yet keep light out.

The end discs may be made of hollow or box form, with two plates perforated, and a baffle plate placed between them so that water can freely pass through the hollow flange to the water spaces formed between the layers of film.

Or the end discs may be made out of a single piece of absorbent material, such as felt, cloth, or the like, or a piece of absorbent material may be placed between two perforated metal plates. Or the end disc may be made hollow with two metal plates and a baffle plate, with an aperture round the periphery for water to enter. Another way of forming the end discs hollow is by two plates separated some little distance apart, and each having raised flanges which form baffle plates when turned towards each other, so that a tortuous water passage is formed through which light cannot pass. Another way is to perforate the two plates, placing the perforations non-coincident, and forming each plate with a rim so that when brought together (one rim being of less diameter than the other), they form a box-shaped disc on the end of the spool.

For flat films a flat rectangular case is made of the usual construction, but with light-trapped water vents in one or more sides or edges of the box, as already described, for the spool flanges. Perforations covered with absorbent light proof material, or baffle plates, are convenient.

The water spaces between the layer of film are formed as follows: in one form either the film or the usual opaque backing strip that forms the wrapper is provided with thickened edges, which, when

the film is laid or wound in superimposed layers, keeps such layers separated sufficiently to allow fluid to pass between. These thickened edges are serrated or cut away at intervals to provide entrances for the developing fluid.

A convenient way of forming these edges is to crimp or emboss raised teeth or dots close to each edge of the sheet—either the edge of the film itself or the edge of the opaque backing strip or of the opaque interleaves—by passing between suitable embossing rollers. Or the edges may be thickened by additions thereto instead.

Between each layer of film is interposed a "developing wrapper," which keeps the films absolutely separated, yet allows the developer to pass between and reach the entire face of every film. The developing wrapper is formed in any of the following or other suitable ways:—For roll films this wrapper is formed as a long strip, on the back of which may be numbers or other indicating marks, and on the front side the strip of film suitably attached by one end.

For flat films the wrapper is formed as a series of leaves, having numbered pull tabs at one end, and a film attached to the front of each leaf by the usual means.

In its simplest form this developing wrapper is made of some absorbent material, in the form of a thick sheet of several thin sheets. Any suitable material may be used, such as pure unsized fibulous paper, such as filter-paper, or blotting-paper; or some textile material, such as woollen or cotton cloth; or some hygroscopic colloid, such as gelatine, agar-agar, or the like.

This plain absorbent sheet wrapper is simple and cheap, and is quite suitable for small sizes or films. It lies in contact with the face of one film layer and back of the next film layer, and if made sufficiently thick, and not pressed or wound too tightly, it effectively sucks up sufficient fluid when placed in the developer, and distributes it evenly over the entire face of the film laying in contact therewith. As such developer is absorbed from the wrapper into the gelatine of the sensitive film, it is reinforced or replaced through capillary attraction by the absorbent wrapper. The process continues until the film is fully charged and development completed.

A more perfect form of this developing wrapper, and one that is better suited for films of large size than the simpler form already described, consists in making it with a series of fine distributing channels over its entire surface, in order to permit of the developing fluid reaching every part of the wrapper more quickly and evenly. Such channelled developing wrapper may be formed of any of the above materials, though gelatine or else absorbent paper is preferable. A convenient construction is to form the wrapper of two or three sheets, either laid loosely or preferably cemented together, one or two, or even three of such sheets having indentations embossed in their faces in the shape of a series of corrugated lines running across the film, or else a series of such lines crossed diagonally, or a series of curved or circular lines crossing and overlapping each other, or else a series of raised dots. In any case the embossed lines or dots are placed very near together, the spaces between being exceedingly small. With such an embossed wrapper the channels or spaces serve to convey and distribute the developing fluid to all parts, and the raised parts serve to transfer it to the face of the film.

In order that these raised parts shall not cause marks on the film and uneven development (though if sufficiently close together they should not), a flat sheet of the absorbent material is placed between the face of the film and the raised part of the wrapper, to act as a diffuser of the developer. This flat sheet is preferably cemented to the underlying embossed sheet, the wrapper thus being formed of two united sheets, but if desired a third flat sheet may be attached to the opposite side, the embossed sheet being enclosed between the two flat ones. Such a wrapper resembles in construction a piece of the well-known "corrugated packing paper," used for wrapping round bottles and other frail articles, and may be easily and cheaply manufactured by passing one sheet between embossing rollers, and then depositing upon a plain sheet bearing cement, or upon a sheet of gelatine before it has set or dried.

The indicating numbers or other marks may be applied as follows: Generally these are a great source of trouble, especially in the case of roll films, as, under certain conditions, such as damp storage, they "set off" and mark the adjoining sensitive film. This is obviated by forming the numbers in the body of the developing

wrapper or the opaque paper. In the case of a wrapper of textile material the numbers may be woven in a different coloured thread.

In the case of paper or gelatine they are preferably stained in the body of the material, with an inert dye, instead of being painted upon the surface with pigment as usual.

Owing to there being no necessity to remove the film from the package for development, and the package being light-tight in itself, the entire package is immersed bodily in the developing solution. A darkened room or enclosed light-proof tank are both unnecessary. Any open vessel may be used, such as a basin, jug, drinking glass, or the like, the whole operation of transference and development being performed in open daylight.

In order to make the improved film package more convenient to the tourist or traveller we may provide it with self-contained chemicals in the dry form, so that upon immersion in water they dissolve. Such a package is a "self-developing film package." The self-developing chemicals may be applied to the packages in any of the following ways:—The necessary developing chemicals, in a suitable dry form, are applied to the package in such a manner that they will never affect the film, even under the influence of damp storage or the like, until the package is placed in water, whereupon the chemicals dissolve and thus form a developing solution of the correct strength and quantity. The chemicals may be applied to the package in several different ways, and either in the form of a paste coated thereon, or a solution soaked in, then dried. For example: 1. To the back of the film, either to the base itself, or to the anti-curling back layer of gelatine. 2. To the opaque layer—preferably combined with the gum or other soluble cement that secures the opaque layer to the back of the film. 3. To the loose opaque layer, if such be used. 4. To the developing wrapper. 5. To some part of the light-tight carrier, such as inside the spool core, outside the enclosing wrapper of same, inside the flat film case, or in any other convenient position. 6. To the air-tight packing case that encloses and completes the improved film package, and which can be used as the developing tank.

Although any of the above ways are feasible and workable, it is best to place the developer in such a position that it cannot reach and affect the film surface during storage, or until placed in water. For that reason it is well to place the chemicals in the form of a soluble capsule, in some convenient part of the package, such, for instance, as in the hollow core of a film spool, or attached to the end of the spool wrapper (the inner end before exposure, which is the outer end after exposure), or inside the enclosing case of a flat film pack (for instance between the plates of the central expanding division).

Probably the best position of all is to place the chemicals in the air-tight packing case that encloses the film package. In that position it is quite away from the film, whilst being used in the camera, but when the package is replaced in the enclosing case the two are brought together again, and, whilst keeping inert for any length of time afterwards without touching the film, the developer can be immediately brought into action upon the film by filling the case to the brim with water. John Edward Thornton, Altrincham, Cheshire.

### New Trade Names.

STANDA (device).—No. 306,006. Photographic apparatus included in Class 8. Standa, Ltd., 3, Cherry Tree Court, Aldersgate Street, London, E.C., manufacturers. September 5, 1908.

TO SOCIETY SECRETARIES.—Those at present responsible for the preparation of a programme may be well advised to make a note of a tour of the societies now being arranged by Messrs. Chas. Zimmermann and Co., of 9 and 10, St. Mary-at-Hill, E.C., for their Mr. F. C. Hart, whose lecture-demonstration deals with the use of the world-famed Agfa products, and particularly with the Agfa flash powder and lamp. Mr. Hart is making a feature of taking a flashlight group of his audience, developing and printing the negative in their presence, and demonstrating the use of certain Agfa preparations in the treatment of negatives and prints. Societies who have invited Mr. Hart speak highly of his services.

### Transferring Prints to Wood.

The value of a small wooden box for trinkets, hairpins, matchboxes, etc., as a gift may be very greatly enhanced (writes Mr. F. Palmer in "The Photographic Monthly" for November) if it is enriched by a portrait of the giver or by one of his pictures. To transfer a photograph to wood which has not been previously sensitised may seem difficult, but as a matter of fact it may be very simply effected in the following way:—

First, clean off the polish on the wood with a rag dipped in methylated spirit, and by means of the finest glass paper get a perfectly smooth surface, free from fluffiness or scratches. Then polish with the common French polish, which is nothing more than a strong solution of bleached shellac in methylated spirit, and may be purchased at any oilshop. As soon as a good polish is obtained stop work; only be sure that the French polish is not used sparingly.

Next take the photograph, which may be P.O.P. or bromide, and, in preference, glossy on thin paper, and soak it in spirit until quite pliable. Lay it face downward on the polished wood, and rub flat and free from bubbles with a wad of wool soaked in spirit. It is now to be set aside to dry hard, and when the spirit has evaporated the paper will be found firmly attached to the wood.

Getting rid of the paper is a little tedious. Dip a piece of sandpaper in lukewarm water and rub away the paper, not merely in one spot, but all over alike. Gradually the paper will wear away and the picture will appear. Great care must be taken now not to rub hard enough to injure it, and when the whole is equally and sufficiently distinct, stop and set aside once more to dry.

After the lapse of a few hours, all night if possible, to ensure the absence of all moisture, apply the white French polish again in the ordinary way, just as if there were no photograph there, and wait until a satisfactory polish is obtained. In this way the picture will be protected against all ordinary usage, and the owner will have a permanent reminder of the giver.

### Group Lighting.

The majority of portraits (writes the "Bulletin of Photography") show one light and one shadow side, but suppose we are required to photograph several persons in a group, it would be very difficult, not impossible, to get pleasing effect with only one light and shadow side. Some of the faces would have the features distorted, the decrease of light intensity towards the shadow side being too abrupt. When we have several figures to illuminate it is advisable to choose the side light regardless of everything else with exception of a small area between the figures and background. This management gives considerable purity of illumination and at the same time an atmospheric effect. The heads should be directed as much as possible towards the top light, by which the countenance becomes possessed of soft graduated half-tones.

Open the top light more or less on the two sides so that the light of necessity gets somewhat around the figure. Skill is now demanded in determining where the shadow of the middle top light is cast. Upon this depends its favourable result. Suppression of light might seem to argue for lengthy exposure, the bane of photographic practice, but experience teaches that harmonious illumination requires less time than when the effect is contrasty. Then there is less contrast in the subject, development may be prolonged and more detail brought out in the shadows than is the case with hard negative.

### Titles on Postcards.

Every amateur maker of postcards (says a writer in "Photography and Focus" for October 27) at some time or other must have wished to be able to print the titles on his cards as neatly as is often seen on the commercial cards. The titles must either be very neatly printed on white card or may be cut out of printed matter and stuck on a card. As a rule a local guide book will be found to contain names of the subjects, and these names are simply cut out with a pair of sharp scissors and mounted on a card. Six or eight names are usually arranged on the card so that all can be photographed together on a quarter-plate. The plate used for this purpose should

a "photomechanical" one (backed). The negative must be fully developed, so as to get the white ground of the lettering as opaque as possible, and if sufficient density is not obtained it may be intensified with mercury. The negative is then cut up into strips each containing a title.

To use one of these strips (presumably stripped from the glass plate. Eps. "B.J.") an opening is cut in the card which surrounds the postcard negative, and the negative of the title is inserted, an opening being also cut in the mask above, so that it may print through. If the title negative is not very dense the borders of this opening may show on the print, but this can usually be prevented by fastening a piece of black paper on the outside of the glass, so that the title does not print while the postcard is being printed. The black paper is then pulled away for just long enough for the postcard to print. The method takes a little trouble, but it gives a much neater result than any other.

### The Swing-Front in High-Speed Work.

The lens is mounted in a special panel (writes Mr. Adolphe Brahm in "The Amateur Photographer and Photographic News" of October 27, speaking of the use of the Adams four-way swing-front) with a suitable bellows. By turning a screw with a milled edge the lens can be tilted on an axis either backwards or forwards; the exact extent of its excursion is indicated by a lever, which points to a mark when the lens is perfectly upright. The panel is rectangular, and, being easily removable and replaceable in any one of four positions, it is evident that a horizontal, as well as a vertical, swing of the lens can be produced. Let me make it definite at once that this swing of the lens does not in any way resemble the "swing" on the so-called "panorama" cameras; a different field is not presented by the tilt of the above adjustment, but a modification of the focus of the same field. The reader who has followed my description of the swing-lens and the reasons for its use in a horizontal direction will readily understand that it will be indicated only in those cases when the foreground and background are not directly behind one another. All focal-plane workers will remember how very seldom the camera is directly opposite any moving object, but almost always obliquely—an excluding, of course, the photography of single figures—a condition which is exactly amenable to the use of the swing-lens. I will describe its use by a single example. One is photographing a race at a corner—a series of runners one behind the other. The fluidity of movement necessitates a lens of fairly high aperture, which only the leaders will be in sharp focus. Standing at a convenient angle I swing my lens *towards the more distant objects*, to focus again on the position which the foremost figure will occupy; and now I have the whole field sufficiently sharp. Although I have written this brief exposition of the swing-lens only for high-speed workers; I do not forget that many of my adherents of the focal-plane shutter do not regard the 1-1,000th sec. exposure as the *ultima thule* of photography; and to these I would commend this useful little adjustment as rendering possible landscape photography with a hand camera in circumstances when stopping down is for any reason impracticable.

### CATALOGUES AND TRADE NOTICES.

**TELLA "BARGAIN LIST."**—The list of the Tella Camera Co., of High Holborn, London, W.C., runs to forty-eight pages, and includes a great variety of apparatus, from reflex cameras down to slip-in mounts. The company offers goods on three days' clear trial, and guarantees the apparatus listed to be *bona fide*, a term which our knowledge of the firm's trading prompts us to substantiate. The bargain list is one worth getting, particularly in view of the firm's special offer to customers at a distance who wish to dispose of their apparatus in part payment.

**ENLARGING APPARATUS.**—A new list of enlarging apparatus and accessories has just been issued by the firm of Lancaster, Birmingham, whose "Multum in Parvo" enlarger was surely a pioneer in similar instruments of this class. Since its introduction the facilities for enlarging which Messrs. Lancaster have placed at the disposal of the amateur have been many and various, notable among them being the convenient illuminating chambers, of which quite a number of patterns are now available. The list, which is very fully illustrated, is certainly one which any one commencing the season's work in enlarging should not fail to get.

## New Books.

"Photography for Young People." By Tudor Jenks. (London and Edinburgh: W. and R. Chambers, Ltd.) 3s. 6d.

The author of this book has evidently sought first of all to impress upon the boy or girl reader the scientific principles on which photography is based. He claims—and rightly too—that he instructs the reader in the practical use of a photographic outfit. So he does, but he alternates a chapter on practice with one on theory, with scarcely an intermission throughout the book. And as both his theory and practice are sound, we cannot but commend this method as quite admissible, since it almost compels the reader to learn not only the methods of every-day photography, but the principles which underlie them. The author introduces his subject by describing the principle of a lens' action, a chapter which we might commend to the individual who recently wrote to a firm of photographic opticians to question a statement of theirs that a certain lens which at  $f/6$  covered a quarter-plate would at  $f/22$  cover a whole-plate. He had repeatedly stopped down in this ratio, but his sensitive film had failed to show any sign of enlargement!!! The operations of exposure and development are very thoroughly treated by our author in several chapters, though the space he devotes to printing processes is scarcely proportionate. He describes the practical working only of P.O.P. and gaslight paper, merely mentions gum, carbon, and platinotype, of which latter his appreciation is scarcely adequate. But he is up-to-date enough not to omit ozobrome.

The plate illustrations might be of better subjects. They are not by the author, and therefore there is no excuse—as this part of the work has been vicariously performed—for a better selection not having been made. Nevertheless, the volume as a whole is an excellent one to put in the hands of a boy or girl of twelve or more years of age as an interesting and instructive work on photography. The writer's style throughout is uninvolved, and the get-up of the book fits it to be a Christmas gift.

"Photograms of the Year 1908." (London: Dawbarn and Ward, Ltd.) 2s. net.

Considering the disadvantages under which the compilers of this annual publication have to work, the result is quite surprisingly good. Pictures are collected and reproduced, and critiques and articles written nearly half a year before the book reaches the hands of the public. A great many of the pictures see the light ultimately in the London Autumn exhibitions, but in some cases it does not appear that the world at large entirely endorses the opinion of the "Photograms" critic who has ventured upon a prophetic opinion so far ahead. In the present volume, for example, we are shown four "thumb-nail" diagrams of the works of Mr. Arbuthnot—an exceptional distinction, certainly, and one with which we should concur if only the object had been to show the paucity of the photographer's design; but when we find these pictures to be mere accompaniments to a page of compliment, highly seasoned with adjectives of admiration, we are forced to believe that an early and private examination of pictures is not likely to be so purely critical and impartial as the examination of things standing their ground upon an exhibition wall. One thing in this "Fragmentary Retrospect" will perhaps help Mr. Arbuthnot out a little. It is a suggestion that his galanty-show horse should be viewed upside down, so that it looks like a tree. We have tried this plan, and honestly affirm that the whole thing is infinitely to be preferred in that position—that is, if the spectator will let his imagination run riot.

The great value of the volume is, in reality, that it shows us a goodly number of photographs that have not appeared elsewhere from various causes. It is pleasant to turn these pages and see the reproduction of pictures by names well known; pictures that but for "Photograms" would have remained in obscurity, most of them for another year at least. Moreover, the book is international, in that it covers quite different and wider fields than do the illustrated newspapers, which only give us again and again the things we have seen often enough. The arrangement, too, by which photographers send in their works first to "Photograms" and thence to the exhibitions, gives us in many cases an interesting peep behind the selecting scenes. Quite a number of the pictures here have

been "rejected," and the cruel-hearted may go through the things that are new to them and endorse the judgment of the committees.

On the whole the outlook upon pictorial photography which this volume affords is more hopeful than usual. There are fewer stupid things among the pictures than there have been in past years, there are plenty stupid enough nevertheless. But picture-making seems to have been a saner process during 1908. Is it that at last all the available freaks are exhausted? To repeat them is certainly more damning than to repeat the old and safe recipes.

The frontispiece facing the title is a portrait by Wm. Crooke. It is as old-fashioned as it can well be, abiding absolutely by all the laws and traditions of art which our American cousins strain their reputations to upset. Yet there is not a lovelier thing than this portrait in the whole book. Its charming subject of a young girl at three-quarter length, standing in profile, but with her face turned towards us, is most effectively lit and simply and prettily posed. Another frontispiece is made by the "Maison Jeanne d'Arc" of F. H. Evans, which is the best thing that the year has produced in photographs of street architecture.

The pictures from abroad are, naturally enough, not so fine as a whole as those of our own country, which still leads in pictorial enthusiasm, a fact of which a perusal of the foreign contributions leaves no doubt. We are much struck by a finely chosen woodland scene, excellent in composition and rich in romantic feeling. This is by Dr. Ed. Leslie Pooler (Australia), who calls it "Sullen Winter." A popular magazine is most successful when "every picture tells a story." Miss Emily Pitchford (U.S.A.) has told hers remarkably well with a couple of back views of young women gazing out of a window. The action supplies the literary appeal of the title "Suspense." Just by contrast we may refer here to J. C. S. Mummery's "Barn Door," which loses a great deal in reproduction. This work relied entirely upon certain atmospheric charms for its effect and intensity of feeling. In actual subject matter it makes no claim, and as its "mood" has escaped the printer, it naturally does not look as well in the cold printing ink as it might. "Bathers," by Louis Fleckenstein (U.S.A.), is probably a "fake." There is something not quite convincing about the view seen through the bathing machine window (if it is really one, they are not like that in this country). The chief bather is a "maiden mid nodings on," who is only visible by the edging of light that catches her contours, making very agreeable lines. The thing is rather a *tour de force*, and we are inclined to think rather more highly of it than the critic of the volume does, even although we believe it to be a composite affair. We leave to our readers the solution of the question as to how Mr. Fleckenstein first of all got himself into the machine with his sitter, in such a prudish place as U.S.A., and how, once in, he managed to keep sufficient distance between himself and the sitter to obtain so nicely proportioned a photograph.

"Paysage Decoratif" is one of C. Puyo's charming figure subjects set in landscape. Each factor is in itself delightful, but it cannot be said that they make a particularly decorative ensemble. The result is characteristically photographic, and the figure seems to want placing much higher up in the picture. A "Decorative Study," by Mrs. A. W. Brigman (U.S.A.) is a circular scheme enclosing a nicely designed figure of a young person photographing a bubble or a celestial orb—something spherical in the distance, at any rate.

The literary contributions from abroad do not make quite such interesting reading as they have done in past years. The same pessimistic note is uppermost, as though the reporters were a little ashamed of the year's harvest, and were disarming criticism by anticipating the scoffs from the Mother Country. F. Mathies-Masuren, writing of Germany and Austria, says: "public interest . . . was just sufficient for a visit to our shows, and since these are now of rare occurrence, the sympathy has gradually dwindled." In Germany the laurels seem to rest with the professionals; in Austria they are falling to the amateurs. In Canada we are told by Sidney Carter that "the consumption of photographic material in large quantities to no particular purpose goes merrily on." He also instances the one touch of nature when he tells us that the attempts of the Toronto Club this last year to conduct an exhibition which would give satisfaction to everybody resulted in many of the best-known exhibitors withholding. Mudie Thomson's article upon South Africa is unnecessarily long and too critical of examples which the reader does not know. A note of hope is

sounded in the affirmation that "South African photography has (during the past year) gained a nucleus previously lacking": a most damning reflection upon 1907 and earlier. Spain would seem to be in the most deplorable condition of all with regard to amateur enthusiasm, yet strangely enough that country makes a very fair show in the illustrations of the volume. Manuel Mendez Leon is also on the look-out for a nucleus—a fresh one, "leaving behind the worn-out old one." He tells us how he was appointed an agent for an American "photographic exchange" for the circulation of albums, etc.: "Well, after working incessantly for a year, advertising in the paper which I direct, I succeeded in getting two subscribers!!"

So the world wags! We sincerely hope that this highly entertaining book may go out to the four corners of the earth and fire enthusiasms and create nuclei to the betterment of all concerned.

"The Light of Asia." By Sir Edwin Arnold. Illustrated with 32 pictures of Indian scenery by Mrs. Mabel Eardley-Wilmot. London: Kegan Paul, Trench, Trübner, and Co., Ltd. 15s. net.

Here we have an *édition de luxe* of Sir Edwin Arnold's great poem of Buddha, the illustrations to which are of photographic origin—that is to say, from the camera of Mrs. Eardley-Wilmot, who in many instances is happy in her choice and rendering of landscapes. It is hardly to be expected that any photographs of any scenes will do much to heighten the charm of this modern classic, but in so far as the photographs convey a sense of the heat and brilliance of the Indian landscape and of the sublimity of the Himalayan mountain ranges, they help the reader to appreciate better the poetical story of the holy Gautama. The volume is beautifully produced, and the photographic reproductions are in almost every case altogether excellent.

## Dew Apparatus, &c.

Rodenstock's "Heligonal" Anastigmat. Sold by Charles Zimmerman and Co., Ltd., 9 and 10, St. Mary-at-Hill, London.

This is a very rapid anastigmat of fine quality, the specimen submitted to us being No. 5 of 8¼in. focal length and aperture  $f/5$ . On a half-plate this lens behaves admirably, and shows no trace of astigmatism at full aperture. The single combination is also an anastigmat, and works well at an aperture of  $f/12.5$ . The complete combination in the specimen we have tested shows a little spherical aberration at the largest aperture, but this quite disappears at about  $f/6.5$ , at which aperture the lens stands the most critical tests. On a careful test on a small point of light will reveal the aberration which is of a kind not at all likely to affect the sensitive plate. The "Heligonal" is an unsymmetrical doublet, the front combination being composed of two lenses only, while the back one has four. The iris is of metal, and the workmanship and finish are excellent. The price of No. 5 in ordinary mount is £8. A 4¼in. lens suitable for quarter-plate camera works at  $f/5.4$ , and costs only £4—from which it is evident that the "Heligonal" is not overpriced. We may indeed, style it a cheap lens, considering its fine quality and its universal utility.

The Busch "Bis-Telar," Series  $f/7$ . Sold by Emil Busch Optical Company, 35, Charles Street, Hatton Garden, E.C.

The original Bis-Telar, working at a full aperture of  $f/9$ , is well known to our readers, and its usefulness as a long-focus lens requiring only a very short camera extension, is fully appreciated. The new series works at the very useful aperture of  $f/7$ , and therefore is much better adapted than the old one to hand-camera work, so that it can fairly class it as a rapid telephoto lens. The one submitted to us is No. 2 of Series 2, with focal length of 10¼in., and a back focus of only about 5¼in. It is listed to cover a quarter-plate, and appears to do this and more with excellent definition at full aperture. It has often been claimed that 10in. is the ideal focal length for a quarter-plate, but few quarter-plate cameras will extend sufficiently to take such a lens. The Bis-Telar is, however, suited to a quarter-plate camera, by reason of the short extension required for the small bulk, which is no greater than that of an 8in. R.R. lens. The price of the No. 2 is £3 in iris mount, £4 in focussing mount, and £5 8s. in Koilos shutter, the other lenses of the series being equally moderate in cost. We may note that while the old  $f/9$  series

included lenses from 7in. to 14in. focal length, the new one, being at  $f/7$ , includes five lenses varying from 8in. to 22in., the extra extension in each case being about  $\frac{1}{2}$ in. more than half the length.

"Hermagis" Applanastigmat and Telephoto Combination. Sold by F. C. Clarkson, Colchester.

No. 7 Applanastigmat of aperture  $f/6.8$  and focal length 210 mms., about 8 $\frac{1}{2}$ in., has been submitted to us for trial, together with an Hermagis tele-objective, to be used with it. The positive doublet lens is to be symmetrical in construction, and it can be used divided, a single combination giving excellent definition. The complete set is a very fine example of an anastigmat, and ranks with the best that show absolutely no astigmatism at fairly wide angles. On half-plate we can detect no signs of this defect. On throwing the lens a little out of focus the existence of very slight residual traces of spherical aberration can be detected, but nowhere is there any indication of a linear focus. The field is very fairly flat, and altogether the lens is one of a very useful and valuable type, and is extremely well suited to a half-plate camera. On testing the combination with the tele-attachment, at a magnification of  $6\frac{1}{2}$ , a most satisfactory result was obtained, the definition being as good as could be wished for, while the exposure was very short, three seconds on ordinary plate being ample exposure, though the working aperture of the whole combination was  $f/44$ , and the focal length 14in., the total projection of the telephoto combination being 8in.

Rapid Table Bromide Printing Machine. Sold by Jonathan Fallowfield, 146, Charing Cross Road, London, W.

This apparatus the photographer is provided with a most efficient means of printing from negatives of half-plate size and under, and that in an apparatus which requires only table room is operated solely by the worker's two hands. In fact, for actual movements of the apparatus itself only one hand is required, the other serving to feed in the sensitive cards or papers

control their removal when exposed. The printer consists of a frame measuring 17 $\frac{1}{2}$ in. by 8in. at its base and standing 22in. to the top of the chimney. It is fitted in one pattern, with both a lamp and an adjustment for gas, the latter being mounted on the side which allows of the gas-burner occupying a central position. Access to this portion of the apparatus is by means of a metal door in the back and a window on each side, which is fitted with glass, and thus enables the lamp to serve also for the illumination of the developing table. The front of the apparatus contains a framework made to carry a half-plate negative, or a carrier in which smaller negatives may be held. This framework is divided by a series of grooves into which a vignetter may be placed in order to produce vignette effects, when necessary. The negative being placed in the frame, the exact subject which it may

be desired to include in the print is selected by removing the right-angled metal piece seen in the drawing, which, after adjustment, is fixed by a set screw, and thus forms a stop for the card or paper, the latter being thus quickly placed in register upon the negative. A light spring, also seen in the drawing, serves to hold the card in position when the pressure back is fully out, but on this latter being thrown completely up the pressure is released, and the paper falls by its own weight into a suitable receptacle placed to receive it. The operation of printing consists simply in sliding the card or paper under the spring and up to the stop, pressing down the wooden knobs of the handle to the full, at which moment the exposure commences owing to the drop of the orange glass screening the light. Exposure is terminated by raising the handle, and, as before stated, the paper is released by completely throwing up the pressure back. It will thus be seen that the apparatus allows of very rapid taking off of prints from the negative, whilst its working parts are reduced to so few that one may reasonably expect its working for a long period without getting out of order. The price of the printer, either for gas and oil or for electric light, is 52s. 6d.

The Thornton-Pickard "A" Model Enlarger. Made by the Thornton-Pickard Manufacturing Company, Ltd., Altrincham.

In this new introduction of the Thornton-Pickard Co., the base, stage, and front of the enlarger are of polished mahogany, the condenser stage being supported by two heavy brass struts, which give

the much-desired rigidity to this part of the enlarger. The stage is built open, and pivoted centrally, so that it can be tilted in either direction, and thus any distortion in the negative corrected by the use of this movement in conjunction with a similar movement of the easel. The clamp which serves to fix the stage at any desired angle also automatically secures it in the perpendicular position. In addition, a see-saw movement (actuated by rack work) of the base of the negative stage allows of the negative being tilted the other way,

this adjustment being more conveniently made by such tilting than by pinning the paper at an angle upon the easel. Rising and falling front and collapsible triple extension condenser cones are provided. The latter allow the lantern body to be brought towards and away from the condenser, the lantern body itself moving on a mahogany base. One little point is worthy of mention, namely, that the focusing pinion is provided with a head on either side of the enlarger,

and is so adjusted that a forward movement of the head moves the lens forward, and a backward movement draws it back, a synchronism which is on all fours with that universally adopted in field cameras, but not invariably in those used for enlarging. Complete, with 5½in. condenser and enlarging lens fitted with rack and pinion adjustment, iris diaphragm, and orange cap, the price of the outfit is £4.

The second illustration shows the B pattern of the "Ruby" enlarging lantern, in which the user's own camera is employed. It is made in quarter-plate, 5 x 4, and half-plate sizes, at the respective prices of £2 15s., £3 10s., £5 5s. Full particulars of this and the other instruments are contained in the newly issued booklet, "Enlargements and How to Make Them," by the Thornton-Pickard Co., wherein is given a useful introduction to the making of enlargements on bromide paper.

## New Materials, &c.

The "Gladiator Extra-Special Rapid" Plate. Made by Mawson and Swan, Ltd., Mosley Street, Newcastle-on-Tyne.

So far as can be judged from the products which come to our table, the activities of emulsion makers of late have been engaged more particularly with printing papers than with dry plates. At any rate, it is some considerable time since any gelatine plate has been introduced in regard to which claims of a notable character have been made. Messrs. Mawson and Swan, however, are one of the few makers—almost the only ones—who confine themselves solely to the manufacture of dry plates, and therefore it was with more than usual interest that we lately received from them samples of a new plate, the "Gladiator," the introduction of which, we understand, is prompted by the desire to offer photographers the fastest plate obtainable, even in these days of ultra-sensitive gelatine emulsions. In accordance with the makers' usual custom, the plates are issued without a speed marking, but the new product has not been announced until both camera and photometer tests had repeatedly proved the correctness of the claims made on behalf of the plates.

Owing to a variety of circumstances our own tests of the plates had to be made under considerable pressure of other duties, but they were, nevertheless, sufficient to show that in the "Gladiator" the makers have reached a degree of sensitiveness which has certainly surprised us, and will no doubt surprise others who put the new introduction to the test. We took the occasion to employ "Gladiators" for a series of landscape exposures in the rather faint light of a recent afternoon. These, though exposed according to the readings of the Wynne actinometer, using a speed number as high as we have ever adopted, proved in every case to be palpably over-exposed, a convincing, if not perfectly regular, proof of the great speed of the plates. The evening of the same day gave us the opportunity for a test which we had on several occasions made with plates of undoubted ultra-sensitiveness. This was a series of hand-camera exposures of figures close at hand, illuminated only by the arc lighting outside shops in the West End of London. The exposures were one-tenth of a second at  $f/4.5$ , and we were gratified in obtaining negatives which came up readily in the developer, and showed far more detail than we had been able to obtain on ordinary (i.e., non-ortho.) plates under similar conditions. Further camera exposures have showed the extreme sensitiveness of the plates, from which it would appear that the makers, in putting forward the large claims for their product, are not magnifying their own results obtained under test conditions. For both indoor and outdoor photography, for portraiture by artificial light, and for all purposes where a full exposure is needed in the minimum of time, the new plates should certainly rapidly come into favour. They are issued at 1s. per dozen quarter-plates, other sizes in proportion.

"ROTARY" CHRISTMAS POSTCARDS.—The Rotary Photographic Co.'s series of P.O.P., self-toning, gaslight, and bromide cards reach our table. The two latter bear, on the address side, suitable designs and greetings in two colours, whilst in the case of the two former the designs are in one colour, and the cards are sold at the ordinary prices. The gaslight and bromide cards are sold at 10s. 6d. per gross, or 74s. per 1,000. The cards possess the customary good qualities of the Rotary Co.'s manufactures.

PLATE-MARKS, BOARDDOIDS, AND FOLDER PORTRAITS.—Since introduction some time ago of their method of impressing a plate mark on a photographic print by the very simple Leto plate-marker the Leto-Photo Materials Co., Limited, have brought out an outfit simply for the use of professionals, and have thereby placed within easy reach of the portraitist the means of producing prints in a highly effective form. The "Boardoid photography," as the Leto Co. calls it, consists in the use of—

The stout (Boardoid) printing-paper—P.O.P., C.C., self-toning, gaslight, or bromide.

The inexpensive Leto plate-markers, issued in eight sizes, from 3½in. by 2½in. to 8½in. by 4½in.

The cover mounts of dark art brown complete, with tissue protector for the photograph.

Thus there is first of all no departure as regards printing save that a Boardoid paper is used, and the negative is masked in printing, so that the portrait appears with a clear margin; secondly, the plate-mark is impressed on the print quickly, and by aid of ordinary copying or dry-mounting press; and lastly, there is no mounting; the prints are touched at one edge with adhesive and fitted in their folders.

The effect of the finished print produced in this way is handsome and extreme. The dark brown of the folder goes particularly well with the tones of the P.O.P., collodion, or self-toning paper, as with the toned bromide or gaslight print. There is a style about the print, an air of expensiveness in the tissue protector, which should enable the photographer to secure a good price for it. Both "vertical and horizontal shapes," a portrait looks somewhat recherché, whilst as for production there is nothing for photographic assistants to learn.

A special offer is made by the Leto Co. in thus first introducing outfits to the profession. On receipt of trade card and a coupon, which is published this week in our advertisement pages, the company will send an outfit of plate-marker, masks, cover mounts, and Boardoid for work in 8in. by 5in. size for the reduced figure of 2s. 6d., the outfit being that usually sold at 4s. 6d. Application should be made immediately to 3, Rangoon Street, London, E.C., and the circular prices of Boardoid papers, plate-markers, and folders obtained at same time.

CHRISTMAS BUSINESS.—Last year Messrs. Walter Pearce and St. George's Press, Brentford, W., issued the booklet, "What Shall I Give?" the use of which by photographers who desired to buy the suitability of portraits for Christmas presents before their customers met with much success—as we happen to know from several of our readers. Even more tasteful in appearance is this year's booklet, "The Choice of a Gift," a piece of printing the like of which the photographer cannot obtain from a local printer. It is a prospectus of blue-grey and blue, and tactfully, yet forcibly puts the case for the photograph as a Christmas gift, the photographer's announcements and illustration supplementing this preface. Messrs. Pearce can supply quickly on receipt of order and copy, and they can also offer copies of the 1907 booklet at a reduced price. In this instance the booklet is supplied by them only to one studio in the district, a guarantee to their customers that the booklet will not be sent out by a competing photographer. Our views of the business value of a piece of really elegant stationery have been expressed before, and over again, and considering the moderate prices at which St. George's Press offer their work, the photographer cannot better than place himself in their hands.

THE HALIFAX PHOTOGRAPHIC Co. advise us that the Greeting series of Lilywhite prize postcards, with the usual emulsions, are now ready. Designs will be sent on application.

POSTCARDS.—Messrs. Droege and Co., 43, Comeragh Road, Vauxhall, Kensington, London, W., send us specimens of the printed bromide cards made by them (for photographers) of P.O.P. tones, either brown or purple. Both descriptions of card present a very effective result, and Messrs. Droege and Co., who execute this work at a moderate rate, guarantee despatch in three days.

CRIPPLEGATE PHOTOGRAPHIC SOCIETY.—In connection with the "one man" shows which are to be a feature of this season, arrangements have been made with E. O. Hoppé, F.R.P.S., to exhibit a few (about 15 or 20) of his pictures in the Lecture Room on November 9, at 7 o'clock p.m. Mr. C. W. Coe will also give a lecture on "Exposure and Development for the Subject."

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

FRIDAY, OCTOBER 30:

Forester Camera Club. "On the Printing, Developing and Toning of Velox Papers." W. F. Slater.

MONDAY, NOVEMBER 2.

Salvern Camera Club. "On the Printing, Developing and Toning of Velox Papers." W. F. Slater.  
South London Photographic Society. "The Right Way in Photography." Messrs. Burroughs, Wellcome & Co.  
Safford Photographic Society. "Exhibition of Thornton-Pickard Prize Slides and Apparatus." R. Hesketh.  
Southampton Camera Club. "Intensification and Reduction." C. M. Cooper.  
Sudley, Farsley, Calverley, and Bramley Photographic Society. "Figure Studies." W. Cohen.  
Safford Photographic Society. "Enlarged Negatives on Paper." Herbert A. E. Hey.  
Telford and Forest Hill Photographic Society. "Lantern Slides." Demonstration.  
St. Albans and District Photographic Society. "View Books." M. Tomkinson.  
Manchester Photographic Society. L. and C.P. Union Lantern Slides.

TUESDAY, NOVEMBER 3.

Weymouth Photographic Society. "The Photography of Sport." Illustrated with lantern slides. Adolphe Abrahams.  
Leamington and District Camera Club. "Design in Picture Making." Walter Barnes.  
Birmingham Photographic Society. "On the Printing, Developing and Toning of Velox Papers." W. F. Slater.  
Weymouth Photographic Society, Y.M.C.A. "Chemicals Used in Photography." W. F. Malikin.  
Walsley Photographic Society. "Walks and Climbs in Switzerland." Percy Lund.  
Suffolk Camera Club. Exhibition of Colour Photography.  
Weymouth and District Literary and Scientific Society. "Home Portraits." Illustrated. P. R. Salmon.

WEDNESDAY, NOVEMBER 4.

Wimbledon Park Photographic Society. "Bromide Enlarging." H. P. Johnson.  
Weymouth Camera Club. Lantern Evening.  
Middlesex Photographic Society. Lantern Slide Competition.  
Suffolk Photo Club. "On the Printing, Developing and Toning of Velox Papers." W. F. Slater.  
Walsley Suburban Photographic Society. "Novel Lighting Effects." H. Essen.  
Weymouth Polytechnic Society. "Holland Pictorially Portrayed." Rev. H. O. Fenton.  
Weymouth Photographic Society. "Slide Making Under Difficulties." Ramsay Traquair.  
Weymouth School of Photo-Engraving, Bolt-Court. A Lecture. Will Rothenstein.  
Weymouth Camera Club. "A Tour Round an Old Garden." Alex. Keighley, F.R.P.S.

THURSDAY, NOVEMBER 5.

Weymouth Photographic Association. "Evolution of a Picture or Art in Photography." Illustrated. George L. A. Blair.  
Weymouth Photographic Society. "On the Printing, Developing and Toning of Velox Papers." W. F. Slater.  
Weymouth Amateur Camera Club. Competition Prints and Lantern Slides.  
Weymouth Amateur Photographic Association. "Lantern Slide Making." Fred. J. Tryhorn.  
Weymouth and District Camera Club. "Orthochromatic Photography." T. W. Derington.

THE CORNISH CAMERA CLUB, Penzance, have elected Mr. R. Pearce, president; Messrs. H. Bradbury, Percy Holman, and A. G. , council; Mr. H. Trembath, treasurer; Mr. H. Stewart, secretary; and Mr. F. Richardson, assistant secretary.

SOUTHAMPTON CAMERA CLUB.—The members of the Southampton Camera Club gathered in goodly numbers on Monday night at the headquarters, on the occasion of the lecture by Mr. Arthur Marshall, F.R.P.S., the lecturer, who had spent the day judging the exhibition of the club, and is one of the most eagerly looked for contributors to the winter programme of the club. On previous occasions Mr. Marshall had taken the members under his wing, and means of his camera to Continental centres, his Spanish pictures Dutch scenes having provided contrast with those of Italy and where. On this occasion Mr. Marshall introduced the members to the Northern Coast of Ireland, and enabled them by means of photographs taken on an extensive motor tour to realise some of the beauties of the Emerald Isle. Evidently the lecturer had made up his mind to exhaust the possibilities of that little known region—the beautiful country which is washed by the Atlantic rollers, for no Irish scenery or of Irish character was missing from his repertoire. The rolling main and the granite-strewn plain gave way to the quaintest little village and the country town, the

wonderful coast scenery and the romantic old ruins, the cathedrals and old-world churches, the monoliths and crosses, all came into the progress made by the distance-covering car, while the fund of dry humour possessed by Mr. Marshall enabled him to bring into life the specimens of Gaelic peasantry who figured on the screen by the way of the slides. Naturally, when Mr. Marshall appears the best of all possible work is expected to be shown on the screen, and there was a most definite opinion expressed that no previous sets of slides shown by the Nottingham artist quite compared with those of the lecture. The magnificent landscapes and extraordinary figure studies, the cloud and atmospheric effects, all told of the master man behind the camera, and the audience were all too soon made to realise that motor tours have at last an ending. Mr. Marshall was most heartily thanked at the conclusion.

LEEDS PHOTOGRAPHIC SOCIETY.—A lecture and demonstration of more than ordinary interest was presented to the members on October 20 at the Leeds Institute by Mr. Thomas K. Grant, of London, upon "The New Autochrome Plate." Mr. Grant gave a very careful demonstration, explaining where mistakes are most likely to be made, and their remedy. The demonstration was followed by a series of lantern slides showing the results of the plate in actual work, and these produced something like a sensation among the audience. The slides were beautiful beyond all words. A formal vote of thanks, in a neat little speech by Mr. F. W. Branson, F.I.C., and seconded at some length by Professor Harold Wager, who stated that a great scientific result had been achieved, was carried with acclamation. A special lantern and new unifocal lens, kindly lent by Mr. F. W. Branson, and the skilful manipulation of the lantern by Mr. A. A. Pearson and Mr. A. Atkinson, contributed in no small degree to the success of the demonstration.

## Commercial & Legal Intelligence.

CHARGE OF THEFT.—At the Hastings Borough Bench last week Thomas Styles was charged with stealing 68 photographic negatives, 119 photographs, and six mounts, together value £4 17s. 6d., the property of D'Jornette Plummer, 56, Western Road, Brighton, between April 20 and June 20.

Prosecutor said the accused had been employed by him in a studio at 28, White Rock, Hastings. The business was sold in June, but prisoner continued with the new proprietor. On Monday, witness went to 3, Pelham Arcade, where prisoner had recently opened a business, and saw displayed in the window photographs belonging to witness. He returned later with Detective-Sergeant Chantler, and they found photographs marked "R. A. P." (the name of his firm), and others marked "Plummer."

Mrs. Ellen Hilder, formerly manageress for the prosecutor, identified all the photographs and other goods produced as the property of the prosecutor or the new proprietor, with the exception of two, which she gave to prisoner. Prisoner had purchased mounts from her amounting to about a dozen in all. Prisoner had the key of the premises once or twice in busy times.

Henry Harcourt Verden, of 11, Goldsmid Road, Brighton, purchaser of the White Rock business, identified sixty-seven photographs produced as belonging to him, and put their value at £2. Witness did not know to whom the negatives belonged.

Detective-Sergeant Chantler stated that on the way to the station after his arrest prisoner said: "There were only a few old postcards that belonged to him. He said he would crush me, and this is what he has done."

Prisoner pleaded not guilty, and was ordered to take his trial at the Quarter Sessions, bail being allowed in one surety of £50, and one other of £50.

BRITTON BANKRUPTCY.—The affairs of Walter William Powell, photographer, late of 414, Brixton Road, S.W., came before a meeting of creditors on October 21, at the London Bankruptcy Court. Mr. Walter Boyle, Assistant Receiver, presided. The Chairman reported that the debtor began the business in March, 1897, with practically no capital, and continued trading under the style of Rupert Leighton until August, 1907. His trade had varied from

£300 to 700 per annum. He agreed to pay £100 a year as rent of the premises, and he hired the fittings, etc., at a charge of 30s. a week. He expended money on the premises, but got into arrears with the rent, and he eventually closed the business. The landlord had re-entered the premises, and had seized the goods there. They were worth about £80, but the sum of £385 was due for rent. At that time he was being pressed by other creditors, and since August, 1907, he had had no regular business. The debtor, who attributed his failure to heavy expenses and bad trade, had filed a statement of affairs showing ranking liabilities £534 13s. 6d., the only available asset being book debts of £12 7s. 8d.

There was no offer of composition before the meeting, and it was stated that an order of adjudication had already been obtained. The case was a summary one, and remained—no resolution being passed—in the hands of the Official Receiver as trustee for administration. Creditors: W. H. Tuck, Cheltenham, £300; Kodak, Ltd., London, £10; Arnott and Co., Leeds, £10.

**A LEEDS BANKRUPTCY.**—Henry Morton Pearce, of 101, Roundhay Road, photographer, carrying on business in the County Arcade as Morton's Star Photo Company, appeared last week in the Leeds Bankruptcy Court. The liabilities were £448, and the deficiency was £389, and the bankrupt said his failure was due to bad trade and heavy rent. He had had numerous temporary shops, but had permanent places of business at Douglas, Leeds, and Sterling. In looking after these he had incurred heavy travelling expenses. The examination was closed.

**LEGAL NOTICES.**—Notices of intended dividends have been given in the cases of Joseph Edmund Bramwell, 38, Beechville Avenue, and lately carrying on business at 124, Westborough, Scarborough, Yorkshire, as a photographer, and Mrs. Mary Ann Osguthorpe, Falconers Road, Scarborough, photographer. The last day for receiving proofs by the Official Receiver (Mr. Donald Sween Mackay, 48, Westborough, Scarborough) is November 11.

A first or final dividend of 2s. 1d. in the £ has been paid to the creditors of Scott Stanley Meale, photographer, Coltishall, Norfolk.

## News and Notes.

**A PHOTOGRAPHIC SOCIETY FOR FOLKESTONE.**—Steps are being taken to test the feeling in Folkestone with regard to the formation of a photographic society. The opinion has been expressed that there is room for a photographic society, and that a good way of inaugurating it would be to hold an exhibition (at which prizes would be offered) at the Town Hall. The matter is in the hands of Mr. Geo. H. Sheaff, Priory Dene, Julian Road, Folkestone, to whom letters or suggestions should be sent.

**"WESTMINSTER" ARC LAMPS.**—In addition to the awards at the Franco-British Exhibition given in our last issue, a diploma for gold medal has been given to the Westminster Engineering Co., Ltd., for their electric arc lamp. Their "Westminster" enclosed type lamp is well known to photographers, and is largely used for portraiture and printing, and also for black-and-white, process, and three-colour work. The Westminster Co. write us that they are always very pleased to show the lamps and give full particulars to any one calling at their works, Victoria Road, Willesden Junction.

**DEATH OF MR. SAVILLE KENT.**—We regret to record that the death of Mr. Saville Kent took place on October 11. Mr. Kent was one of our best-known naturalists, and though perhaps not so widely known in photographic circles as many a man of far slighter claims to recognition, was also one of our most able natural history photographers and three-colour workers. The deceased gentleman spent a large part of his time abroad, and at home was never an exhibitor of his work, though his lectures on the scenes and scientific results of his travels will be remembered with pleasure by many. While engaged in 1893 as Commissioner of Fisheries to the Government of Western Australia, Mr. Saville-Kent sent to London a large collection of the stony corals peculiar to the Australian coast-line. These specimens, added to the extensive series indigenous to the northern and eastern districts of Australia previously contributed by him to

the Natural History Museum, constitute the most complete collection of Australian Madreporaria yet brought together. We understand that in recent years Mr. Saville-Kent's attention was given to artificial cultivation of pearls in the large pearl-oyster.

**THE PHOTOGRAPHER IN MUNICIPAL LIFE.**—Bexhill-on-Sea is in the throes of an election. For the seventh year (according to the "Daily Mail") the acting Mayor, Mr. James Glover, who provides the local amusements, is a candidate for the principal ward, his opponent being Mr. Hicks, a local photographer. Mr. Hicks has issued as his poster

VOTE FOR HICKS  
AND MORE ENTERTAINMENTS.

To which Mr. Glover has issued the good-humoured counterblast

VOTE FOR GLOVER  
AND MORE PHOTOGRAPHERS.

**CRIMINAL FACES.**—A daily paper reports that in an address last week at the opening meeting of the session of the Ethnological Society on the right method of dealing with crime and criminals, Sir Robert Anderson, late Chief of the Criminal Investigation Department, Scotland Yard, referring to the so-called criminal type of face, said that on one occasion when Max Nordau visited him he put before him two photographs which were so covered that only the faces were visible. One was that of Dr. Temple, the then Archbishop of Canterbury, and the other that of Raymond, the prince of criminals of his time. The Archbishop's face, said Sir Robert, when in repose had an expression which might almost be termed sinister. Raymond had a remarkably kindly, intelligent face. Max Nordau, who told that one of the two photographs was that of a prominent English public man, would not express any opinion as to the types.

**HACKNEY PHOTOGRAPHIC SOCIETY.**—The following lectures, &c. will be given during the Hackney Society's Exhibition:—Wednesday, November 4: 7.30, Opening by the Mayor and Mayoress of Hackney; 8.30, Concert; 9.30, Lantern lecture, "By the Severn Sea," A. Linford, B.Sc. Thursday, November 5: 7.30, Concert; 9.30, Lantern lecture, "In the Moselle Valley," W. L. F. Wastell, F.R.P.S. Friday, November 6: 7.30, Concert; 9.30, Lantern lecture, "On the Thames" (Autochrome slides), J. McIntosh, F.R.P.S. Saturday, November 7 (Exhibition open at 1 p.m.): 7 p.m., Concert; 9 p.m., Distribution of awards; 9.30, The competition slides.

**M. MAURICE MEYS, of Boulogne-sur-Mer, whose exhibits of Autochrome transparencies at the recent exhibition of the Society of Colour Photographers will probably be remembered by many of our readers, is announced to deliver a lecture on colour photography at the Grafton Gallery, Grafton Street, W., on October 31, at 3.30 p.m. M. Meys has made a special study of the Autochrome plate, and lecture should, therefore, prove of considerable interest to workers in this branch of colour photography.**

**CINEMATOPHONES IN SOUTHERN RUSSIA.**—Exhibitions of cinematograph pictures have become an established type of entertainment in the Crimea. Kieff, says the British Consul in his annual report of the trade of that town for 1907, and there are now from twelve to fifteen "theatres," where from six to seven performances, each of an hour's duration, are given daily. The supply of films comes from Paris, although many pictures depict scenes in the United Kingdom.

**EXHIBITION OF COPPER PANELS.**—Messrs. Panels, Limited, of Darnley Street, Birkenhead, are now holding an exhibition of specimens of their new method of reproducing prints and pictures in the form of copper panels, at the Manchester Hotel, Aldersgate Street, London, E.C. The panels can be made of almost any size up to 12 in. long by 3 ft. wide, and are suitable for the decoration of hotels, public buildings, ships, or private houses. The exhibition, which opens on October 27, may be visited daily between the hours of 11 a.m. and 7 p.m., till November 7.

**ABERDEEN PHOTO ART CLUB.**—"Bromoil" was the subject of a demonstration given before the members of the Aberdeen Photo Club last week by Mr. William Mackay. Mr. James T. Jeffrey presided and introduced the lecturer, who in a very able and instructive manner explained the process, the theory, and the advantages and difficulties. He showed by the practical side how the maximum amount of control could be got by this process, which although it is to the question of pure photography, has as its start a photographic basis.

## Correspondence.

We do not undertake responsibility for the opinions expressed by our correspondents.

Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

### A CAUTION.

To the Editors.

Gentlemen,—In your "Situations Vacant" column of last week there is an advertisement from St. John's, Newfoundland, for a lady retoucher, stating that board can be obtained for £1 15s. per month. I don't know what sort of board it can be at this price.

My experience has been that it is impossible to get board in St. John's under \$20 per month. I have lived in St. John's, Newfoundland, for over thirty years, and ought to know something about the place. A young lady in a strange country wouldn't feel very satisfied with the salary offered after she had found out the facts as to the cost of living.—Yours faithfully,

W. PARSONS.

147, North End, Croydon.

October 26, 1908.

## LANTERN SLIDES AND BROMIDE PRINTS DIRECT IN THE CAMERA BY REVERSAL.

To the Editors.

Gentlemen,—There seems one point in Mr. Carnegie's experiments which he has evidently overlooked or not given sufficient consideration—viz., that if the exposure has been through the glass, as in the Autochrome plate, the reversal is easier and more complete, the image being on top of the film; whereas, in ordinary exposure, by contact or through the camera, film to lens, the image is at the bottom, that is, nearest the glass, and if Mr. Carnegie will try a lantern plate of almost any make, exposing in the camera, glass to lens, he will find reversal with potass permanganate or persulphate of ammonium, nearly, but not quite, as successful as with an Autochrome plate.

The cause of this comparatively easy reversal of the Autochrome is this: A plate exposed through a colour filter is much easier of reversal than one exposed without a filter. I found by experiment that an Ilford lantern plate, exposed through an orange-red filter, with reversed exposure, was easily reversed without veil, whereas a plate exposed without, showed on reversal a great amount of veil. I therefore came to the conclusion that the colour filter plays an important part in the successful reversal of a plate.

Perhaps I may mention a method I practised years ago for producing reversed negatives. It gave very satisfactory results, provided the negative was a plucky one. An Ilford lantern plate was exposed by contact with a negative in the printing frame. It was developed in the usual way with hydroquinone, and when fully out exposed to white light, and development continued until the positive was converted into a negative, the veil being afterwards removed by a weak hypo and ferricyanide reducer.—Yours truly,

Thornton Heath,

E. FENSKE.

October 24, 1908.

LANCASTER PHOTOGRAPHIC SOCIETY.—The annual exhibition will be held at the Friends' Hall, Fenton Street, from November 23 to 26, inclusive. In the open classes silver and bronze plaques will be placed at the disposal of the judge, Mr. Tulloch Cheyne, for award. All pictures and slides will be submitted to a selection committee, who reserve the right to select the best work in the case of limited space. All entries, however, will pass before the judge. Loan exhibits, for which no fees are payable, are also invited. Entry forms, duly filled in and accompanied by entry fees, must reach Mr. J. Holt, 11, Fern Bank, Lancaster, not later than November 14, the latest date for receiving pictures being November 18. Entry forms and full particulars may be obtained from the Secretaries, Mr. J. Holt, 11, Fern Bank, and Mr. W. Gorst, 23, Market Street, Lancaster.

## Answers to Correspondents.

\* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.

\* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.

\* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

### PHOTOGRAPHS REGISTERED:—

H. S. Franks, 60, Strand, London, W.C. Four Photographs of a Draped Figure. G. H. Beckworth, 42, New Park Road, Salford. Photograph entitled: "A Freak of Nature."

H. W. West, The Hollies, Birmingham Road, Kidderminster. Photograph of the Pulpit in St. Mary and All Saints Parish Church, Kidderminster, and Photograph of the Altar.

T. S. Wilson, 541, Lincoln Road, Peterborough. Photograph of the Interior of St. Paul's Church, Peterborough.

H. C. Turner, 46, James Street, Harrogate, Yorkshire. Two Photographs of Captain A. Boyd-Carpenter.

LANTERN-SLIDE TRANSFERS.—Could you please do me a favour by letting me know what firm could supply me with transfers for making lantern slides?—ALLEN BERRESFORD.

Messrs. W. Butcher and Sons, Ltd., Camera House, Farringdon Avenue, London, E.C.

CRYSTOLEUM.—Can you inform me, through the columns of your journal (1), whether there is now any agent for the crystoleum process who either sells the materials, or (2) executes paintings in the process? (3) I believe the "Alstona" Company had a similar process, but cannot find its address or whether it still exists.—AQUARIUS.

1 and 3. We believe the "Alstona" Company is still at 36, Albemarle Street, W. 2. We know of none, but we imagine a small advertisement under "Miscellaneous Trades" would put you in communication with those doing such work.

NO-COCKLE.—We are not aware that formulæ for this solution are published. We have no experience of them, and we believe the preparation is a secret.

C. WILLIAMS.—We are sorry we can only refer you to the colours sold specially for the purpose. We do not know what is the composition of the medium in question.

ALBUMEN PROCESS.—With reference to your article on "Fineness of Grain and Micro-photography" in "B.J." of October 16 last with regard to working the albumen process, I should be most grateful if you would inform me if certain back numbers of "B.J." for the year 1902 or 1903 are obtainable, which, I understand, contain full working instructions for working the albumen process by the modern method, a *résumé* of which can be found in the "Année Photographique, 1903," under the signature of L. P. Clerc, said to be translated from the original English articles; but I should certainly prefer the original working instructions.—EXCELSIOR.

We think the articles to which you refer are those on "The Albumen Process in Practice," which appeared in our issue of April 3 and 24, 1903.

ETHELBERT.—We can best advise you to study the advertisements in our pages, from which you will see that retouching is almost always required, except from operators of the best order, and they should have been through it. If you have a situation at present we advise you to keep it.

PRESS PHOTOGRAPHY.—Can you advise me the best way to get subjects in the Press at home and abroad? Is there any society that accepts subjects and sends them to the most likely papers for publication, or would you advise sending or taking them direct to

the publishers? As I live within 50 miles of London, if you can give me a few hints as to Press work they will be much appreciated?—PRESS INQUIRY.

We advise you to get "Photography for the Press" (Dawbarn and Ward, ls.). The Illustrations Bureau, 12, Whitefriars Street, E.C., is in a position to offer your work in all directions. You had better write them.

**SLIDE-MAKER.**—The process was given as described in a contemporary. We have not the original publication by us, but we suggest that a better process is to employ gold toning on a slide developed to a warm brown colour. If you address the Ilford Co. they can refer you to their instructions for this process in connection with the use of their "Alpha" plates.

**STAIN AFTER INTENSIFICATION.**—I should be grateful if your ever useful query column would assist me in the following:—I intensified a negative with mercury and ammonia, but as the white clothing was too dense I put hypo on it, but, being in a hurry, used it very strong. This has caused a brown stain, and the resulting print is patchy. How can I get over the brown stain? If I dyed the negative a yellow colour would that do?—BROWN STAIN.

We do not think you can do anything to remedy this state of affairs. The ammonia and hypo between them have probably taken out all the silver, so there is nothing but a mercury image left. The stains may, however, be due to incomplete action of the hypo, in which case a second bleaching, again followed by hypo, might remove them. If this fails, you might try staining, but we doubt if it will be any good. Retouching would probably be the best and safest expedient.

**DEVELOPER.**—Please say if I can make a stock solution of No. 1 "Imperial Standard" developer, and if so, how much metol, metabisulphite, bromide, and water I would add to ½oz. pyrogallol acid, so as to have a stock solution, of which I would take, say, 3oz. to water 20oz.?—J. A. C.

In order to retain the proportion between the various chemicals you require to take as follows:—Pyro ½oz. (equals 220 grs), metol 180 grs., metabisulphite 480 grs., bromide 80 grs.: in other words a solution of four times the normal strength if 20oz. of water are used. As we gather that you require a solution about seven times (20 divided by 3) the normal strength, you require to use only 12oz. of water, but we fear that you will find it impossible to make a solution of this strength.

**SPECIAL PUTTY.**—Will you kindly let me know the address of the firm who sell a special sort of putty for studio roofs? I cut the address out, but cannot now find same.—PUTTY.

Carson and Sons, Grove Works, Lombard Road, Battersea, S.W., whose paints are so well known, make the putty about which you inquire. Any of the oilmen will procure it to order if they do not keep it in stock.

**GELATINE RELIEFS.**—I use Nelson's gelatine with bichromate of potash, but I cannot get the intaglio or the raised block high enough or low enough for what I want. I have gone through Pretsch process, Placet's, Woodbury's, Foxlee's, Michaud's, Poitevin's Autotype, Swan's, Sutton's, and the Meisenbach, given in the "Photographic Almanac," 1893. Is there anything else I could mix with the gelatine, such as gum or glue, to get my depth or raised block higher still. I run plaster casts of them?—S. WOOLY.

Your trouble may be due to more than one cause. It may be brought about by the bichromate film being dried too slowly, so that it has to a great extent lost its property of absorbing water and swelling up. No addition to the gelatine is necessary. The trouble may, and probably does, arise from the employment of unsuitable negatives. Unless they are very vigorous and strong, it will be impossible to get very high relief in the gelatine. See the article on another page.

**STUDIO QUERIES.**—1. I wish to know the most suitable tank developer for studio purposes chiefly. I am also puzzled about a new studio I am going to build. I have several books on the subject, but they all differ. 2. Suppose I have a studio 14ft. wide and as long as I like, say 30ft., what length would you have the glass side, 10ft. or more? Robinson says the whole length, but

that, I think, is not necessary. 3. The studio is 14ft. wide. It is necessary to carry the glass more than 7ft. across? This is a very common way, but the sun is so nearly vertical that it would shine in for a very long time.—W. T. H.

1. The following is given as a good tank developer for studio work: Pyrogallol acid 20 grains, sodium sulphite 120 grains, potassium metabisulphite 130 grains, sodium carbonate 240 grains, water 40 ounces. 2. We should prefer to have 12ft. of glass at the side—that will be quite sufficient. 3. Seven feet will do very well. Both designs are good, but in your case we should advise the one shown in the first sketch to that of the second.

**H. J. CHARMAN.**—Better apply to the exhibitor, Mr. C. P. Butler, Solar Physics Laboratory, South Kensington.

**E. D. F. B.**—We can tell you that neither workers pin their faith to the particular scheme. No details of their regular practice are available, probably because they have no precise method.

**A NURSE'S ORDER.**—Some months ago I received an order for a number of cabinet reprints from the nurse of some children whose portraits I had taken, and requesting that the photographs, with the account, should be addressed to the father of the children. I did so, but up to the present, although I have made repeated applications for payment, I have not received any reply. What I should like to know is, who is responsible for the debt, the nurse who ordered the photographs, or the father to whom they were sent, supposing that parent existed, for I have never seen him myself, the previous orders having been paid for at the studio by the nurse? They have since removed from here, so I presume I should have to take out a summons in the district where they now reside.—DOUBTFUL.

We are afraid that we are not clear as to the circumstances. If the nurse gave the order and was responsible for payment in the first instance, she is responsible now; but if the father was your customer in the first instance, you had no right to supply copies to the nurse except with the permission of the father. I should surmise that it is the father who is ordering in each case, but in the absence of a distinct understanding to this effect, I do not see that you can do anything.

**POSTCARD RIGHTS.**—A few months back I sold a firm in the town a set of views, with permission to reproduce on certain styles of postcards. Lately I have been requested to supply some more prints of these same subjects, as they tell me that some of the ones they had earlier have got damaged, and cannot be used again, and they want to make the set complete to enable them to publish another series of a different kind. Now, as I did sell them originally the sole right, but only permission to reproduce on a certain style of card, am I entitled to another fee for each of the views for this new series? My own opinion is that I am, but I should like your opinion on the point. I have always understood that when a fee is paid for permission to reproduce when the purpose it is wanted for has been served, that the fee transaction, and if the view is wanted again another fee should be charged.—QUERY.

Certainly, you are at liberty to grant right to reproduce the way you describe, and the firm should abide by the agreement.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

### SUMMARY.

Dr. E. König communicates a practical article on the making of stereoscopic "anaglyphs" similar to those of Du Hauron, but employing the pinatype process in conjunction with two new dyes, complementary to each other, just worked out in the Hoechst works. (P. 848.)

At Birmingham last week the Deputy-Stipendiary dismissed an action brought by an ex-soldier for the return of £20 said to have been deposited by him with a photo-printing company as surety when taking a situation as collector. The defence was that the £20 was premium for teaching the business, but the magistrate's clerk remarked that it was "a lot of money to pay for rather trifling teaching." (P. 857.)

A recent paper by Mr. A. J. Bull shows the remarkable differences in the various grains, regular and irregular, employed in photo-mechanical printing. (P. 850.)

The most recent particulars of the now largely used thiomolybdate method of toning are contained in the patent specification which appears, with other "Patent News," on page 855.

Those who have need to bring solutions up to a working temperature may find the memory rule given in the article on page 847 service to them.

### "COLOUR PHOTOGRAPHY" SUPPLEMENT.

Dr. J. H. Smith has further examined a number of natural oils and compounds occurring in them, and has classified them as sensitizers and de-sensitisers for the bleach-out colour process. (P. 81.) Pure xylol is advised by Dr. W. Scheffer as the best reagent for the removal of the complete Autochrome film from its glass support. (P. 87.)

Baron von Hübl, in discussing the properties of the Autochrome plate in relation to the reproduction of one Autochrome from another, concludes that the want of "saturation" in colours is the chief difficulty in the way of a perfectly satisfactory reproduction. Radiation phenomena may also occur. (P. 82.)

Dr. R. Luther, in some notes on the use of the Autochrome in stereoscopic photography, gives rules for trimming after cutting separate pictures, and also raises the question of the possibility of colour errors due to parallax when using a wide-angle lens. (P. 85.)

The Society of Colour Photographers, at its annual meeting last week, had a satisfactory report and balance-sheet presented to it. (P. 88.)

M. Meys, on Saturday last, delivered a lecture, before the Anglo-French Association in London, illustrated with much of his Autochrome work. (P. 88.)

### EX CATHEDRA.

#### The Traill-Taylor Memorial Lecture.

The eleventh Traill-Taylor lecture will be given by Dr. E. Wandersleb, of the scientific staff of Carl Zeiss, at 66, Russell Square, on Tuesday, November 17, at 8 p.m., and the subject will be "The Regulation of the Rays in a Lens System." We may assume that this title will cover the description of the action of a lens from the most modern German points of view, and as these points of view are very little understood in this country, the lecture may be looked upon as one of very great importance. The German method of considering how a lens acts is widely different from the usual English method and is far simpler. For expository purposes it is ideal, and those to whom optics, as usually taught, is one of the most obscure sciences can very quickly grasp all the essential facts. The more modern method is, of course, derived from the theories laid down by Professor Abbe, which no one can be better qualified to expound than Dr. Wandersleb. This will certainly prove to be a most important lecture of the series, and may be expected to attract a large audience. Admission is free by ticket obtainable on application to Mr. J. McIntosh, 66, Russell Square, W.C.

#### "Ausführlich Angegeben."

The sentiments which inspired the two joint monarchs of the kingdom of Barataria to sing of the "satisfying feeling that their duty had been done," very similarly convey a sense of gratification to editors who find their aims understood and appreciated abroad as well as at home. And an expression of such appreciation perhaps comes more frequently from the Continent than from the phlegmatic Englishman. This fit of self-congratulation, we would explain, is induced by the arrival on our table of the current issue of Dr. Eder's "Jahrbuch," the annual of photography which does for scientific and technical Germany what the "B.J. Almanac" in a more popular way does for less scientifically disposed readers in the English-speaking countries. Dr. Eder, in his quotations from the contemporary press, constantly uses the phrase at the head of this article in regard to the articles in the "British Journal of Photography," and a glance through his pages justifies the present claim of the "B.J." to "deal in detail" with the current progress in photography—a claim which is not exaggerated in the phrase coined as an advertisement headline: "The journal with the reading in it."

\* \* \*

#### The Camera and Lost Umbrellas.

We learn that photography has been put to a new use at Exeter. A photograph was recently taken of a number of umbrellas which careless passengers had left behind in the tramcars.

The umbrellas were ranged singly in a large shed at the tramway depot, and came out with great clearness. This photograph was reproduced and published, surmounted by the invitation to the public, "Do you recognise your own?" As a direct result of this pictorial effort, a large number of the umbrellas have been returned to the rightful owners. The tramway officials had in hand a stock of 150 of these lost articles before taking this means of rapid restitution.

\* \* \*

#### Another Cinematograph Catastrophe.

Unfortunately we have to record another cinematograph catastrophe, which happened at Lille, in France. On Sunday evening a large audience, mostly composed of children, had crowded into one of the numerous cinematograph establishments in the town. While the entertainment was in progress, some unprotected films caught fire, filling the hall with thick smoke and flames. A fearful panic resulted, and though these places are under strict police supervision, and the proprietors compelled to provide several emergency exits, these latter proved wholly inadequate. The cries of the children were heartrending, many of them being trampled and so badly crushed that it is feared some of them will never recover. It is to be regretted that such painful incidents as these are not infrequent occurrences. They inspire the general public with fear for what has proved itself not only an interesting, but also an educative entertainment, with all possible precautions. The use of material such as celluloid is bound to give rise to occasional conflagrations, and it is to be hoped that it will not be long before cinematographists are in possession of a non-inflammable film.

\* \* \*

#### The Permanent Commission of the Congress of Photography.

M. E. Wallon, on behalf of the permanent commission of the Congress of Photography, which has its headquarters in Paris, has addressed to the president of the Association Belge the suggestion that the Congress should hold its 1910 meeting at Brussels at the time of the International Exhibition, which will be held in the Belgian capital in that year. M. Wallon suggests that in this way photography would be represented in the Exhibition, and that, as at the previous meeting held at Liège, the question of photographic science, practice, and art might be discussed at the Congress, particularly in regard to the employment of photography for documentary and record purposes. Such applications as these, it may be interpolated, are discussed with particular fitness at Brussels in view of the work of this nature carried by the Institut Bibliographique et Photo-

graphique. It is the intention to divide the sittings the course into three sections: one to discuss theoretical and scientific questions, standards, etc.; another, matter of photographic practice and art; and a third, the employment of photography in record and bibliographic work, and it is hoped that the Association Belge and its president, Captain van Bever, both of whom were largely responsible for the success of the Brussels Photographic Congress of the United Kingdom, will lend their aid to the suggested Congress of 1910. In fact, we understand that a proposal of the permanent commission has been accepted in principle by the Association Belge, and that details will shortly be arranged in Paris in regard to the Congress there in 1910. We understand that the Belgian Government has already given its official adherence to the International Exhibition.

#### Pocket Spectroscopes.

A pocket spectroscope is a very useful instrument to the photographer as it enables him to test his own dark-room safe-lights and filters for himself. Many plates are wasted through placing reliance on unreliable ruby glass and media the deficiencies of which could be detected in an instant with the aid of a small and cheap spectroscope. Those unfamiliar with the spectrum are, however, very likely to make mistakes. They may know that a screen passing green but blue is safe for a particular plate, but when it comes to actual test they are very likely to be greatly puzzled to determine where the safe green light of the spectrum ends and the unsafe blue light begins. Or, again, when a simple filter is in question they may fail to detect the difference made by the filter, which is sometimes very small to the eye. In cases such as these it is a great advantage to have comparison spectra, that is to say, only half the spectroscope slit is covered by the light filtering medium, and two spectra are formed side by side, one being a complete spectrum of the light source while the other shows clearly the effect of the filter. The slit of the spectroscope, however, very short, and if the light filter is bound up with paper or framed this expedient is impossible. A comparison prism is then wanted. This consists of a small rectangular total reflection prism arranged to cover half the slit and to reflect through that half the light derived from the other side source. Pocket spectroscopes are listed with and without these comparison prisms, but the average type of instrument fitted with the extra prism is not well adapted to screen testing. It is really intended for comparison of two different lights, and if it is to be used for screen work two exactly similar lights are required, one being examined through the screen and the other directly. This is very inconvenient, and for screen testing it is better to make a little addition to the spectroscope in the form

### THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1909.

Edited by GEORGE E. BROWN, F.I.C.

THE forty-eighth annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published on December 1. This year's ALMANAC reached a total of over 1,000 pages, and the entire edition of 25,000 copies was sold out immediately. Of no other photographic book ever issued can two such unique facts be recorded. The edition for 1909 will also consist of 25,000 copies.

The editorial article will deal very completely with the important subject of

#### REFLEX CAMERAS,

and the systematic review of the work of the year under the title "Epitome of Progress" will be a strong feature of the volume.

The lines followed in the previous editions of the

ALMANAC will be maintained in general, but in a number of particulars the arrangement of the volume for 1909 will be modified to make it more than ever the book of universal photographic reference.

The ALMANAC for 1909 will appeal to photographers the world over as a daily reference guide in practical work. The standard matter and formulæ will be revised and added to where necessary, and, wherever practicable, new features of an informative nature will be added.

**NOTICE—IMPORTANT.**—Our publishers ask us to inform agents that it is advisable to place their orders for copies immediately, as considerably over half the issue is already booked, and a second edition will not be printed.

a side mirror set at an angle of 45 deg., so as to throw the light on to the comparison prisms. A dentist's mirror mounted on a wire handle will serve admirably, for the wire can easily be bent into a clip to fit the tube of the spectro-scope. With this addition both spectra are formed by the same light source, and we can place the filter against the end of the spectro-scope without obstructing any of the light that reaches the mirror. The effect of even the weakest filter can then be instantly detected, while that of a strong filter can be accurately compared with the spectrum of the unscreened light.

\* \* \*

#### Focal-plane v. Lens Shutters.

The question is often asked, What advantage has the focal-plane shutter over a lens shutter working at the same speed? and the correct answer, of course, is, Greater efficiency. Somehow or other a doubt seems to have arisen with some workers as to whether there is not some peculiar virtue attached to the focal-plane method of exposing in the case of high speed work, quite apart from the question of efficiency, but there seems to be no reason to suppose that this is the case. The focal-plane shutter is capable of giving much higher speeds than any lens shutter yet devised, but when both types of shutter are giving the same duration of exposure, they will give equally sharp images of an object moving at a certain speed, the only difference being that the focal-plane image is more fully exposed than the other when high speeds are in use. Suppose we have an object moving at such a rate that no part of it will bear an exposure over 1-200 sec. without showing movement. The lens shutter working at that speed will expose the whole image at once, while the focal-plane shutter will expose it in sections; but this fact cannot possibly make any difference to the sharpness of the image, for no part receives either less or more than the 1-200 sec. in either case. The focal-plane exposure will, however, have a full efficiency of nearly 1-200 sec., while the efficient exposure with the lens shutter will probably be nearer 1-400 than 1-200 sec., but this is the only advantage that the focal-plane exposure will possess. Against this we must set the matter of distortion. The image produced with the lens shutter will be correctly drawn, while the other will be more or less distorted, owing to the fact that one end of the plate is exposed before the other. In the case of a running man, for example, a lens shutter will expose head and feet simultaneously, while the focal-plane shutter, if it runs downwards, will expose the feet before the head, and so represent them in an earlier phase of movement. On this account, therefore, the focal-plane shutter is at a disadvantage. Modern lens shutters of the best type have a very high efficiency at low speeds, as Mr. Chapman Jones pointed out some time ago, their time of opening and closing is the same at all speeds; therefore at low speeds, such as tenths or fifths of a second, the focal-plane shutter has little, if any, advantage. It is only at speeds over, say, 1-20 that its benefits begin to be felt, and then they are confined to high efficiency until we get to the speeds that are beyond the capacity of lens shutters. With modern plates and modern lens shutters a great deal can be done that a few years ago was only possible with the focal-plane shutter, though when using the high speeds it is necessary to guard against under-exposure.

#### THE ADJUSTMENT OF TEMPERATURES.

THOUGH the relative warmth of solutions is recognised as an important factor in all photographic operations, there are some simple matters concerning temperature and its control that are not generally understood by photographers. For example, the fact that a developer should be used at, say, 60 degrees F. may be fully appreciated, while the equally important fact that the developer will not remain at that temperature unless the air in the room is also at 60 degrees may be forgotten.

The temperature of water or of a solution always tends to approximate to that of the room in which it is kept, hence the frequently given advice to let the water stand for some time in the room in which it is to be used. Sometimes a work-room is hotter than it need be, while in winter it is very frequently colder than is at all desirable. In such cases it is difficult to keep solutions at any steady moderate temperature unless special appliances are to hand. When temperature is excessive, the simplest method of obviating its effects is to shorten the times of the operations and use alum or formaline to prevent gelatine troubles, but when the cause is too low a temperature the difficulties are greater. We can, of course, use hot-air baths or hot-water dishes to keep our solutions up to a certain temperature, but, generally, it is simpler, and in the long run probably cheaper, to provide some means of warming the room. In any case, we cannot develop with cold solutions, and, whether the room is warmed or not, we must have a supply of water of normal temperature. If compelled to work in a cold room, we must start with our developer at about 65 degrees, and endeavour to keep it at that temperature as long as possible by any means convenient; while, if the room itself is between, say, 50 deg. and 70 deg., we can work with solutions at the room temperature and moderate our procedure slightly to meet the conditions on the principles advocated by Mr. Watkins with his special time developer.

In an artificially-warmed room, however, the water supply may be very cold, perhaps 40 degrees F., and we cannot keep enough water standing in the room to obtain a good supply at normal temperature. If, however, we have hot water available and understand the proper use of the thermometer, it is quite easy to obtain a supply at the room temperature at any moment. To do this we want a thermometer hanging up in the room to give the air temperature, and a chemical thermometer for solutions reading up to pretty near the boiling point of water. Also, we want a good size graduated measure. Suppose, now, we find that the room temperature is 60 degrees, and that of the tap water 45 degrees, while a supply of hot water to hand is at 120 degrees, we can take these temperatures in a moment or so with our thermometers, and in another minute we can have a plentiful supply of water at 60 degrees if we only know how to go to work. The method is simplicity itself, but probably few photographers know of it. The tap water being 45 degrees and the hot water 120 degrees, the difference between them is 75 degrees, and to obtain water at 60 degrees we must mix enough of each to raise the cold water 15 degrees or lower the hot water 60 degrees. To do this we simply add 15 parts of hot water to 60 of cold, and so obtain 75 parts of water at 60 degrees.

The rule followed is obvious. The number of parts of hot water that we take is equal to the number of degrees that the cold water has to be raised, while the parts required of cold water are equal to the number of degrees that the hot water is to be lowered. In the example the 60 parts of cold to 15 of hot are, of course, equivalent to

EDINBURGH PHOTOGRAPHIC SOCIETY.—Two excellent one-man exhibitions are being arranged by the Edinburgh Photographic Society, at their rooms at 38, Castle Street, the first by Mr. William Crooke, from October 31 till November 14, 1908; and the second by Mr. J. A. Annan, Glasgow, from March 31 till April 14, 1909. As both these gentlemen are amongst the foremost workers in the country these exhibitions should be of much more than ordinary interest. The exhibitions are open daily from 10 a.m. to 10 p.m.

4 to 1, and in all cases it is easy to arrive at very simple reduced proportions, for a small variation in quantities will only give a minute and quite inappreciable variation in temperature.

If compelled to work in a cold room we can regulate the water temperature in the same way, but it is generally advisable to adjust, in the first instance, to 65 or 70 degrees to allow for the subsequent fall that must follow. To obtain water at 65 degrees by the rule given we should have to add 20 parts of water at 120 degrees to 55 parts at 45 degrees, or 4 parts to 11. To obtain water at 70 degrees we should mix 25 parts at 120 degrees with 50 at 45 degrees, or 1 part with 2.

An extra precaution is advisable in a cold room. A cold dish of porcelain or glass will bring down the temperature rapidly, therefore the dish should be warmed first to about 65 or 70 degrees, and this is best done by allowing it to stand for some little time filled with water at about 80 degrees. It is not safe to heat it over a lamp unless precautions are taken to prevent its becoming too hot, for if over-heated it will raise the temperature of the developer and probably damage the film. Then, again, the dish should not be put down on a cold surface when in use, otherwise it will cool rapidly. A piece of cork carpet or cork mat, or a thick piece of felt, should be under the dish, and in very cold weather it is just as well to put another piece of felt or thick, warm, dry cloth right over the dish, which must, of course, be covered to keep out dust derived from the cloth.

Development and toning are the operations most seriously affected by temperature. Most other operations,

such as fixing, are simply slowed down, and a very much longer time than is usual is required to fix a plate in very cold weather. It is, however, only a question of time to produce a complete and perfect result. All the same, there is no reason why the operation should not be hastened by using a warmer bath, and if the hypo is kept in a stock solution its temperature can be brought up by dilution with hot water. To do this we apply the same rule as that given for altering the water temperature by dilution, but we have to vary the working somewhat, seeing that a definite strength of hypo solution is required. Suppose the stock solution to be double strength and at a temperature of 40 degrees, hot water at, say, 120 degrees being available as before, we want to raise the temperature of the hypo solution 20 degrees—that is, up to 60 degrees—therefore, according to the rule, we should add 20 parts of hot water to 60 of hypo solution. We shall then want 80 parts more water at 60 degrees to reduce the strength of the bath, and this must, of course, be taken from the stock of water at normal temperature.

Perhaps we may state the rule for dilution in a different and somewhat simpler form for the benefit of those not familiar with it. Find out, first, how many degrees the cold water is to be raised, and then take that number of parts of hot water. Next find out how many degrees the hot water is to be lowered, add to it that number of parts of cold water. The hot water first taken is cooled down slightly by the measure into which it is poured. We leave it for a minute or so and then take its temperature, this cooling down is more or less accurately allowed for.

## STEREOSCOPIC PROJECTION BY THE PINATYPE PROCESS.

In Eder's "History of Photography," page 432, it is pointed out that D'Almeida published a method of stereoscopic projection in Paris about 1858. He provided a magic lantern with a red and a green glass, each of which he used in projecting the stereoscopic transparency. The observer was likewise provided with red and green glasses, in order to observe the stereoscopic image. In 1891 Ducos du Hauron patented his so-called "anaglyphs," in which he likewise used red and green spectacles in order to obtain the stereoscopic effect of pictures printed, one upon the other, in red and blue colours. It will thus be seen that this description of stereoscopic print is in no way new. The fact that it is very seldom seen at the present time for projection purposes is doubtless due to the fact that it is a matter of comparative difficulty to prepare the two complementary transparent pictures. The pinatype process may be named as an assistance in this direction, as it allows of perfectly transparent positives being obtained in a series of colours. The dyes employed for this purpose must be as closely as possible complementary, forming white by additive mixture. This condition is fulfilled by a pair of pinatype dyes—red F and green M—only to a relative degree. Red F allows a good deal of blue to pass, as does also green M, so that a perfect white is not the result of their mixture; moreover, the colour of the green M is not very pure, and it is therefore not possible to cause the image obtained with this dye to disappear completely on observation with a similarly dyed glass. And this is the essential part of the process. The eye provided with the green glass should not be enabled to perceive the green image, whilst the red should look as black as possible, whilst to the other eye, that provided with the red glass, the red image should be indistinguishable, and the

green image should appear black; that is to say, each should be enabled to see only that image intended for it in order to secure the stereoscopic effect. Of late, success has attended our efforts to find a pair of dyes which would be quite suitable for stereoscopic projection. The absorption band of the "complementary green" extends from the extreme red up to wave length  $570 \mu\mu$ , that of the "complementary red" from about wave length  $780 \mu\mu$  to the ultra-violet. The two dyes together transmit the whole spectrum in the case of an observer using a pair of spectacles the glasses in which consist of a pair of films prepared from the two respective dyes. On the other hand, any image prepared with either of the dyes appears black when observed through the complementary colour for the reason that the absorption bands of the dyes are without gaps.

For purposes of stereoscopic projection it is also necessary, as above remarked, to have two complementary-coloured images and a pair of observation glasses made, say, into the form of a pair of spectacles. The light source must be as bright as possible, for the reason that a good deal of light is lost by absorption in the glasses.

### Preparing the Transparencies.

The transparencies are projected so that they are superimposed, and of a size about 8.5 by 10 cm. In order to obtain the two pictures equally sharp they must both lie, as far as possible, in one plane. This is obtained either by printing one image on glass and the other on a piece of film, or by still, by making positive transparencies in the camera, and from one a reversed positive. It is well known that

\* A weak bright band in the extreme red is of no importance for these purposes.

atype process gives a positive print from a positive, and method to follow, therefore, in using this process is to pare from the stereoscopic negative two positive transparencies on a gelatino-bromide lantern-plate. This can be in the usual manner by contact printing if one of the components is made on film. The film, which must be coated with pure unhardened gelatine, is treated exactly as print-plate described later. One drawback of the film is it never lies completely flat between two glasses, and before a very thick film requires to be used. Further, the mold is liable to ignition in the heat of the projection.

On these accounts we prefer to prepare two positive transparencies, one the opposite of the other as regards right left, so that they can be placed film to film. It is a plan to work so that the negative made with the right-lens is placed with the film side outwards, that is, away the lens in the carrier of the reducing camera; it is adjusted to the desired size, the camera carefully fixed, exposure made. On the film side of the other negative taken with the left-hand lens) a clean sheet of glass is of the same thickness as the plate, and the two fixed the carrier so that the glass plate is turned towards the and the second exposure made. The result is that we have two transparencies the image in which is exactly the size, but one reversed as regards right and left relatively the other. The transparencies should be soft and full of detail, plucky or brilliant results being quite unsuitable for process. In order to avoid confusion it is well to denote the image obtained with the right-hand lens of the camera as (red) the other as G (green). For printing from the transparencies the so-called pinatype print-plates are prepared according to the well-known prescriptions.\* Exposure is made about half the time necessary for collodion paper, the plates well washed, and then stained up as follows:—

#### DYE BATHS.

Complementary red, D .....	1 gm.
Water .....	100 ccs.
Complementary green, D .....	2 gms.
Water .....	100 ccs.

Plate marked R is stained red, that marked G green. Colour is taken by the plates very quickly, and therefore should be constantly kept moving in the dye bath. The images may be adjusted after the plates have been rinsed with water. The images should not be too dark. The correct relative intensity is obtained when the red image, viewed through the filter, appears as dark as the green image viewed through the filter. If the image is too soft it is a sign that exposure is too short, whilst excessive hardness of the print is a sign of over-exposure. The plates, when sufficiently dyed, are placed under a spray for a second or two, and then placed out a minute in 3 per cent. alum solution, again briefly rinsed, the surface wiped carefully with soft cambric, and the plates dried. The two plates are then mounted so that the images in each transparency is approximately in register, as to say, the distant portion of the right-hand print lies a little to the right of the left-hand print; they should not be in absolutely exact register. If the images are too far apart it is difficult to make the projected images register. The pair of transparencies is united by means of an elastic band, cut down to the standard size and bound up in the way with paper or linen binding.

#### The Observation Filters.

The stereoscopic effect of these two-colour pairs can be seen at the aid of a projection lantern. This is done by holding before the right eye a blue-green glass and before the left eye a glass of orange-red. In this case the green image should be seen, that is to say, that turned towards the eye. The compound transparency is turned the other way, the

position of the observation glasses should be changed. If necessary, the light-filters employed for three-colour photography can be used for this purpose, but it is better and more convenient to employ a pair of spectacles containing suitable coloured glasses or gelatine films. Unfortunately, the gelatine films are very liable to injury by damp, becoming distorted and losing their transparency. They are also easily scratched, so that it very soon happens that the pictures cannot be plainly seen through them. Glass to which has been applied a coloured gelatine or collodion film suffers from almost these same drawbacks, but the ideal apparatus for the purpose is a pair of spectacles provided with spectroscopically correct cemented thin glasses. These can be obtained in the most simple way by staining two fixed and well-washed lantern plates in the dye solutions up to a point when they are found by test to be of the right intensity, quickly rinsing, hardening with alum, and again rinsing and drying. In preparing a great number of such glasses the following process is preferable: Well-cleaned thin glass is coated with dyed gelatine solution (see "Natural Colour Photography," by König and Wall), to the extent of about 7 ccs. of gelatine per 100 square cm. area. After drying, two such dyed glasses are cemented with Canada balsam, although cementing is not absolutely necessary. As the dyes "complementary red" and "complementary green" cannot be readily prepared in large quantities in the pure state, so that it is impossible to guarantee the absolute uniformity of their strength, it is preferable to employ for the preparation of the filters other colouring matters which resemble the pinatype dyes as regards their absorption properties but in other respects are not suitable for that method. For the red filters the following formula may be used:—

Gelatine .....	6 gms.
Distilled water .....	100 ccs.
Solution of Rapid Filter Red I. (1:40 in water) .....	200 ccs.

The mixture for the green filter is as follows:—

Gelatine .....	6 gms.
Distilled water .....	100 ccs.
Naphthalin green solution, chem. pure (1:100 in water) .....	5.10 ccs.

The spectacles for use by daylight should be 10 cm.; for projection purposes, 5 cm.

In regard to the projection of the transparencies, it should be noted that the latter should be placed in the carrier so that the green picture faces the light source, and the spectacles so used by the observer that the right eye looks through the green filter, the left eye through the red. The effect of such projection slides is most remarkable. The picture appears to stand out solidly from the screen, and gains still more in depth as the observer is able to take a position a good distance from the screen. If the light source is not very strong it is better to have the pictures a little smaller, as brilliance of the picture on the screen is quite necessary for the best effect.

It need scarcely be added that the red and green images can also be prepared on paper. For this purpose all that is necessary is to apply to the red print-plate a sheet of transfer paper until a sufficiently strong image has been obtained, remove it, and then apply it to the green print-plate, so that the red image of the distance in the subject is approximately in register. The print is then fixed in alum, washed, and dried. Such pictures correspond precisely to the "anaglyphs" which are used to see in the stationers' shops; the effect can never be so good as in projection, nevertheless such pictures possess much interest.

To those who may feel impelled on reading these lines to arrange an evening of stereoscopic projection, the excellent treatise of Dr. W. Scheffer, "Anleitung zur Stereoskopie," may be recommended. The reader will there find a very complete exposition of stereoscopic projection, though not of the preparation of the slides.

Dr. E. König.

## NOTES ON PHOTO-MECHANICAL GRAINS.

(A Paper read before the London and Provincial Photographic Association, October 22, 1908.)

Most photo-mechanical processes produce in the prints a grain which is characteristic of the process, and which is influenced by the method of printing employed. Printing methods readily fall into three classes, which we may designate relief, surface, and intaglio printing. In relief, or typographic printing, the parts that are to receive ink stand up to a common level—that of the type—as does the wood block, while the whites are etched down below this level. Here the practical advantage is that such a block can be printed with type matter; and as in this method of printing it is a question of printing the full amount of ink or no ink, the varying tones of a picture are imitated in the half-tone block by various-sized ink-carrying dots. Surface printing, including collotype and lithography, depends upon a surface tension effect, whereby a flat surface takes up ink from the rollers in varying quantities dependent upon the amount of water present; while in intaglio printing the roughness and depth of a copper plate determines the amount of ink it retains after inking up and wiping, the ink being then transferred to damp paper in a copper-plate press.

### Typographic (Relief) Printing.

In relief printing the effects of light and shade have to be simulated by different sized dots or lines. The process mostly used for accomplishing this, almost to the exclusion of others, is the half-tone block made with the cross-line screen, which has two sets of opaque lines, equal in width to the spaces between, crossing at right angles. The familiar grain given by this is seen in No. 1.

Other forms of regularly ruled screens have been tried, but have not come into general use. Among them may be mentioned Levy's four-line screen, now no longer made, and one screen which has two sets of rulings crossing at 60 deg. The grains produced by these in the prints are shown in Nos. 2 and 3.

The basis of the action of the cross-line screen is that when it is placed in front of the plate, so that the ratio of the effective aperture to the real camera extension is the same as the ratio of a screen opening (side of the square) to the distance of the screen from the plate, then the positions on the plate immediately under the centres of the screen openings receive the full amount of light from the lens, and, owing to the penumbral shadows of the rulings, these bright points shade away to minima under the intersections of the rulings. This gives rise in the negative to dots growing outwards from all the bright centres, the sizes of which are determined by the brightness of the image at the place in question. This geometrical distance is frequently spoken of as the one which is theoretically correct, but this is by no means a complete statement. It is true that it secures a gradation of the light between certain maxima and minima as indicated, but this occurs only in two perpendicular planes about the axis if a round stop is used. In other planes the ratios are not identical, but the fulfilment of this condition of the lens and screen apertures bearing identical ratios to the camera extension and screen distance respectively does produce negatives, such as are required, with one exposure from bright originals, like glossy bromides, but the screen distance has to be altered for differing originals, or corresponding alterations made in the exposures.

It does not appear probable that diffraction plays much part in the formation of the screen negative, for a diffraction pattern does not become at all certain for larger actual aperture ratios than  $f/100$ , as the stop does not approximate sufficiently to a point source. Further, this effect does not depend on the

camera extension, but only on the size of the screen opening and its distance from the plate. If one works on the system of keeping the ratio of the camera extension to the effective aperture, 64, and also the same relation between the screen opening (side of the square) and the screen distance, then the diffraction pattern on the plate is that of a black cross showing that the first dark bands from each edge have a width midway, the four bands joining in pairs to form a cross. As the intersection of this cross is the centre of the dot formed on the negative, it is evident that the effect is not large enough to be felt at the aperture employed. An effect of more consequence is scatter of the light in the film. It is this which makes it so difficult to obtain good screen negatives on plates possessing a coarse grain.

Among early methods for obtaining the translation of type into different sized ink-carrying dots or lines, Petit's is of interest. The grain of this is seen in No. 4. Here a planotype cast was made from a gelatine relief; this was blackened and ruled through with a V tool in a series of parallel lines. The second set, not quite so deep, were generally ruled across these at right angles. The black-and-white effect so obtained was reproduced photographically. Within the last few years a method on similar lines has been used by Amstutz, who wraps his Akrograph wraps a celluloid sheet tightly over a camera print on a metal cylinder, and then cuts a long, close spaced, with a V tool in the celluloid; the depth of the cut is determined by the relief of the carbon print. The fine spaced lines give a single line effect in the print (No. 5).

To some, the regular rows of dots are objectionable, when they cannot be distinguished. It is assumed that, particularly in the reproduction of art work, the regularity destroys some of the artistic qualities of the original. This idea, the desire to produce some revolutionising invention, has caused a number of irregular-grain processes to be put forward. Whether any of these will obtain much vogue is doubtful, but so far none have come into very general use; and, except for some art work, the ruled screen is likely for some time yet to hold its own, especially for newspaper and catalog work and the illustration of technical works where the precision of detail is of importance. Grain processes are apt to impart some character of their own to the print, and frequently give somewhat chalky effects, owing to the dots being of more than one size and the smaller ones etching away in the light tones.

No. 6 shows the grain produced by Wheeler's Metzger screen, one of the commoner irregular grains.

The Spitzertype process, No. 7, is interesting in that it is stated that the grain is obtained by printing from an ordinary continuous tone negative on to a copper plate coated with chromated colloid, no grain of any kind being employed. Immersion, however, in ferric chloride, the mordant tank, and film and penetrates only through a number of pores, instead of evenly over the surface, and thus gives rise to a grain which can be used for printing. The examples put forward as produced by this process certainly exhibit an unusual grain of round dots. Such a process would seem to obtain its grain from the cellular structure of the colloid itself. This structure (a transparent and apparently homogeneous gel) has been demonstrated to exist by the treatment of albumen or gelatin with mercuric chloride, or with alcohol. It is the cause of many well-known phenomena, as, for instance, when plates are dried too rapidly by alcohol they are liable to show an opalescence due to the fixation of the structure, possibly the inclusion of gas bubbles. Again, a gelatin negative hardened in formalin remains permeable while

wet and swollen, but when once dried, it will not swell again so readily, nor be easily permeated by water. The most probable explanation of this is that the formalin fixes the cell walls without closing the cells; on drying, the cell walls crush together too firmly to disentangle on re-soaking. It may be that the Spitzertype grain is derived from this structure.

#### Surface Printing.

In both lithography and collotype there is little or no relief, the distribution of the greasy ink being determined by the amount of water the plate retains, for as the water and grease do not mix, their surface tensions prevent any spreading of the ink to the parts of the printing surfaces retaining much water. No. 8 is the grain of a lithographic print where lithographic chalk has been used for drawing on a stone grained with sand. No. 9 is a coarse collotype grain.

The collotype grain is a quite characteristic network (see No. 9), of which only a thin outline is seen in the highest lights. It is often considered that the character of the grain varies from the lights to the shades, but from an examination of a number of grains there would appear to be an outline network of approximately the same size all over the plate; it is said to be a fine or coarse grain, according to the size of this outline network. This constitutes the highest relief of the grain, and is, of course, most swollen in the whites. In the lightest tones only the ridge of this network carries ink in an irregular manner; the darker tones are formed partly by the network widening, and also, in most cases, by a secondary network of lower relief commencing to print. Both of these effects can be seen in No. 9. In the deepest blacks both systems merge to a solid mass.

As to the manner of formation of this grain. It is often assumed that the grain is formed during the exposure (or at least that the exposure seriously modifies its character), or during the subsequent swelling in water. Its formation has also been likened to the folding of mountain ranges, but the case differs from this in that the collotype film is securely fixed to a firm base, and the elevated strata forming mountains have not a firm base, and are subjected to lateral pressure. Recently an explanation has been attempted, to the effect that the grain is formed during the washing with water by the swelling of an assumed layer of comparatively soluble gelatine under a top film of insoluble gelatine; though why the latter should be wrinkled, and not merely raised (as, for example, in the ordinary carbon print), and why the network should be fairly regular in size, is a trifle difficult to understand from this cause. I consider, however, that the grain is not formed in the swelling, for it can be seen in the collotype plate before exposure, when this is carefully lighted obliquely. Further, when thick gelatine plates are being coated, a grain of this kind can be seen to form on the surface while the bulk is still liquid. This may be due to any attractive force between the solid particles of gelatine as they are formed, such as might be furnished by the surface tension between the solid and liquid gelatine. Any such action would have an effective radius which would influence the size of the outline mesh.

As regards the collotype plate this grain is certainly present when the plate is first made, however it may be intensified by the later operations.

#### Intaglio Methods.

No. 11 is illustrative of the grain of ordinary photogravure where the grain is obtained from the bitumen dust as usual, while No. 12 is an example of machine-printed photogravure showing a screen pattern. An inverted photogravure process is illustrated in No. 11. Here a positive carbon print is developed on the grained copper instead of a negative one as usual, and the etching is carried deep enough for the printing to be done from the surface (typographically) instead of the hollows, as usual.

A. J. BULL.

## Photo-Mechanical Notes.

### Half-tone or Colour Screens.

A METHOD of making lined screens for half-tone block-making or for screen-plate colour photography has been patented by W. C. Masser, of Wigganhall Road, Watford, and W. Hudson, of Hatfield Street Works, Stamford Street, London, S.E. It consists in cutting up films into thin threads or bands and applying the latter to another film. According to the description in the patent specification (No. 25,730, 1907), the films or layers can be coloured transparent or opaque—e.g., one transparent and the other opaque; or the first layer or film can be yellow, the next red, and the third blue, with or without transparent or opaque layer between, or in any order in which they are placed after cutting.

The threads are led on to the screen so as to occupy parallel positions, or in the case where cross lines are desired they may be led so as to lie across each other at any special angle, but being preferred in such a case to use several films or sets of films so that the threads from one film or set may be led and arranged over those of the same or different kind. In such a case a film may be made as above described and then passed again through the pressure rolls to receive the second set of threads, the film being led in at the requisite angle to give the desired crossing to the threads or lines. Instead of forming cross lines in this manner two screens may be formed with parallel lines as before described and then superimposed as is usual with ordinary engraved screens.

The angle of the lines relatively to the sides of the screen may be varied either by directly varying said angle when applying the threads or afterwards by suitably cutting the sides of the film.

According to another method a number of films in the form of discs may be clamped together on a spindle and rotated against a knife applied to the circumferences of the discs, so that a shaving composed of a large number of threads is obtained. These threads may be applied to a carrying film as before described. A number of screens manufactured as above described may be superimposed to form a block, cross sections or shavings of which may be cut off in planes at right angles to the planes of the individual film which shavings may be used as screens having a square or irregular grain.

### PHOTO-MECHANICAL PATENTS.

The following patent has been applied for:—

**COPPER PLATES.**—No. 22,577. Improvements relating to a method for engraving, toning, stippling and etching on copper plates. Carl Quensel, 20, High Holborn, London.

**PHOTOGRAPHS OF THE FRANCO-BRITISH.**—During the last week the was displayed in the Congress Hall of the Franco-British Exhibition a collection of 300 photographs of scenes or objects in the exhibition. The photographs had been sent in in response to an invitation from the exhibition authorities, by whom nine prizes were offered. Those who took part in the "Great Congress" of September 1 were, we understand, invited to take part in this exhibition, or, any rate, had it brought to their notice; yet the results seen upon the stands at Shepherd's Bush last week formed a collection including much that was as bad as it is possible for photographs to be. Apparently everything sent in was shown. But if there had been an elimination of the unfit there would have been but few photographs left. An attendant, whom we found swinging his legs from a table, answered our inquiry as to his having been told off to guard the exhibits in the affirmative. On our suggesting that the money paid for his services was in excess of the value of the exhibits, he was understood to say that he knew which he would sooner have. But he excepted—as did we—from this comparison a set of lantern slides by Newton and Co., which were on a level with this firm's highest standard of excellence, as were another set labelled "by Mr. G. J. Freshwater," but obviously the work of our genial and talented friend who for many years past has acted as technical manager Messrs. Newton and Co.

## Patent News.

*Process patents—applications and specifications—are treated in Photo Mechanical Notes.*

The following applications for Patents have been received between October 19 and October 24:—

**CINEMATOGRAPH.**—No. 22,117. Improved cinematograph. Marius Auguste Ginoux, 322, High Holborn, London.

**COLOUR CAMERAS.**—No. 22,249. Improvements in cameras for taking colour photographs. Alexander Hutson, 6, Lord Street, Liverpool.

**CINEMATOGRAPH-PHONOGRAPH.**—No. 22,415. Pneumatic apparatus for effecting the synchronisation of a cinematograph and a phonograph. Casimir de Proszynski, 72, Cannon Street, London.

**SLIDING CAMERA.**—No. 22,543. Improved folding camera, with self-adjusting objective board. Wilhelm Kabelitz, 322, High Holborn, London.

**WAX-ROOM LAMPS.**—No. 22,571. Improvements in and relating to candle lamps for photographic dark-rooms. William Wallace Beasley, 63, Onslow Road, Richmond, Surrey.

### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

**THIOMOLYBDATE TONING OF BROMIDES.**—No. 22,218. 1907. The invention consists in the use of thiomolybdate compounds in place of sulphides in the sepia toning of bromide or other prints. A typical salt which is quite suitable for use as a toning reagent is ammonium thiomolybdate  $(\text{NH}_4)_2\text{MoS}_4$ , which is practically odourless in freshly prepared solutions. To make up a toning solution from this salt for use in place of the usual sodium sulphide toning solution, a 1 per cent. aqueous solution of the salt is made up, and about 60 minims or drops (1 drachm) of this are used, to one ounce of water to which 5 minims or drops of strong (.880) ammonia are added; or  $\frac{1}{4}$  grain of the solid  $(\text{NH}_4)_2\text{MoS}_4$  may be dissolved in one ounce (fluid) of water, and 5 minims of .880 ammonium hydrate added to form the toning solution. The silver image developed on the print is bleached in the usual manner and is then toned by the ammonium thiomolybdate solution of approximately the strength above set forth, and the action has been found to be intensifying to a certain extent so that flat or dull prints can be considerably improved by the toning process. The intensifying action is apparently due to the fact that, besides converting the bleached image into silver sulphide, the thiomolybdate also deposits on or the image a certain proportion of sulphide of molybdenum. It is found also that the thiomolybdate toning solution will act well with gaslight prints, and there is no tendency to produce the unpleasant yellowish tone above referred to in connection with the sodium sulphide toning.

After the print has been toned in the thiomolybdate solution it is rinsed, and then the whites or high-lights in the print may be given a creamy colour, which can be left if desired. If, however, the whites are to be cleared, which is generally advisable, this can be effected by using a bath of dilute ammonia of a strength of about 1 per cent., and after being immersed in this bath for a few minutes and then thoroughly washed the prints should come out with the whites quite clear.

If by mistake too strong a solution of thiomolybdate has been used, the film of the print may become somewhat stained. The stain, which is yellow, can be cleared by the use of a solution of alkaline metabisulphite, preferably sodium or potassium metabisulphite.

In some cases the bleaching is effected by a solution of potassium iodide and iodine, in which case the bleached image consists of silver iodide; in this case there is usually blue iodide of starch smeared on the print, and this should be cleared with sodium sulphite, as is usual, before toning. The thiomolybdate toning bath will usually remove the blue colour to a certain extent, but perhaps not completely in the ordinary duration of the toning operation. Sometimes the bleaching is effected by means of potassium bichro-

mate and hydrochloric acid, in which case silver chloride is formed on the print. The thiomolybdate toning solution can be used in such cases, but does not give nearly so good tones as when the more usual potassium ferricyanide and potassium bromide bleaching solution is used.

If the normal tone given by the thiomolybdates following the instructions given above is not quite what is required, darker tones are obtained by a shorter time in the toning bath, and warmer tones or a more prolonged action of the toning solution. The normal tone may be taken to be that given by about five minutes in the toning solution. Also if on drying the print is too dark it may be modified by re-bleaching, washing, and again immersing in the toning solution. The toned print will not entirely bleach in an ordinary bleaching solution, but five minutes' treatment with it is sufficient to greatly alter the final tone, though the visual effect of the second application of the bleacher might be slight. Increasing the proportion of ammonium hydrate in the toning bath is also a simple method of producing warmer tones.

It may be mentioned here that, although it is stated in Watts' "Dictionary of Chemistry" that solutions of thiomolybdates when dilute, and especially when free alkali is present, become turbid and decompose, yet the inventor has found that dilute solutions of thiomolybdates, such as ammonium thiomolybdate  $(\text{NH}_4)_2\text{MoS}_4$ , keep very well when made slightly alkaline with their own alkali, ammonia in this case. Solutions of thiomolybdates made alkaline with their own alkali keep excellently if they are concentrated.

The molybdenum may also be replaced in some cases by other metals of the same group (Mandeleeff's Group VI.), such as tungsten and uranium. Experiments have shown that ammonium dithiooxytungstate  $(\text{NH}_4)_2\text{WS}_2\text{O}_2$ , can be used satisfactorily as a toning agent in solutions of approximately the strength above suggested for ammonium thiomolybdate, and good sepia tones are obtained. It is best, however, not to mix ammonium hydrate with the thiooxytungstate in the toning bath. The thiooxytungstates, however, are not as good as the thiomolybdates as regards freedom from odour in solution, and the tones they give are not so good as a rule. Salts in which uranium replaces the molybdenum have been tried, such, for instance, as potassium thiouranate, but these salts are practically useless for toning purposes. Harry Edmund Smith, 3, Ezra Buildings, Ezra Street, London, E.C.

**MERCURY-VAPOUR PRINTING APPARATUS.**—No. 25,511. 1907. This invention has for its object to provide a portable apparatus or stand for supporting both the mercury-vapour lamps and the printing frames in such manner that the lamps can be readily adjusted for taking photographs or for printing without being removed from their stand. The apparatus comprises a metal frame forming a skeleton box or cage having detachable bars from which the printing frames are suspended by detachable clips. The bars are capable of being fixed at different heights or swung out of the way of the frames or rays of the light. A removable top is fitted to the cage, which thus forms a table, the whole being mounted to run on castors. The lamps are supported by a tubular stem or pillar fixed to the back of the cage and formed in two parts, one of which slides in the other, such parts consisting of a lower or socket part fixed to the cage and an upper part removably held in the socket. On the stem an arm is mounted to slide, from which the lamp frame or carrier is so suspended by an adjustable swivelling joint, that it can be moved towards or away from the stem or pillar, tilted and set at any suitable angle for exposure work.

In order to ensure easy working the arm from which the lamp frame is suspended is connected, by a cord passing over a pulley on the top of the tubular stem or pillar, with a counter-weight arranged to slide in the stem.

By sliding the arm up and down the rod the lamps are raised into the required position for exposure work or lowered into the cage for printing. To regulate the amount of current the lamps shall take and to adjust the burning on various voltages or supplies of electricity a regulating rheostat or resistance with ammeter in circuit, is fixed in a convenient position on the table stand. Oscar Thomas Banks, 49, Mortimer Street, London, W.

**ENLARGING AND COPYING CAMERAS.**—No. 9,349. 1908. The claim is for an apparatus comprising a "screen-room" and means for adjustably supporting a screen or plate therein; a lens frame mounted outside the "screen-room" and opposite an aperture in

the front wall thereof; a guide board supported independently of the "screen-room," but capable of being shifted in and out of the latter and adapted to enable the main lens frame to be slid from within the "screen-room" for the purpose of adjusting the focus of the lens; a copy-frame; bellows connecting the camera frame with the aperture in the front wall of the "screen-room"; small bellows and an attached lens frame and lens carrier enclosed in the main bellows, sliding on a stand and adapted to allow of the extreme movement of the lens towards the screen, otherwise prevented by the thickness of the lengthy main bellows. Alohanan Cohen, 69, King Edward Road, Hackney, London.

The following complete specification, etc., is open to public inspection before acceptance under the Patents Act, 1901:—

**SCREEN-PLATE.**—No. 20,111. Screen or plate for direct colour photography and process for manufacture of the same. Soc. Anon. des Plaques et Papiers Photographiques A. Lumière et ses Fils.

### New Trade Dames.

**PARLYTE.**—No. 306,516. Chemical substances used in manufactures, photography, or philosophical research and anti-corrosives. Thomas Parsons and Sons, 8, Endell Street, Long Acre, London, W.C., varnish and japan manufacturers. September 28, 1908.

**ROTOCHROM.**—No. 35,871. Coloured photographic reproductions and coloured photographs. The Rotary Photographic Company, Ltd., 12, New Union Street, Moorfields, London, E.C., manufacturers. August 29, 1908.

## Analecta.

*Extracts from our weekly and monthly contemporaries.*

### Drying Developing Paper Prints Without Curl.

I recommend a method of drying prints (writes J. B. Luttbeg, in "Abel's Photographic Weekly" for October 3) that has been tried out and can be endorsed as having much merit. Prints dried by my method will remain absolutely flat under all conditions, and can be used for loose mounting and folder work by attaching prints to the mount at the upper corners.

The principle of the process is to dry the prints in a roll with the emulsion side out. This keeps the emulsion stretched while drying, and when the dry prints are removed from the roll there is no tendency to curl.

Wooden rollers of the desired length (say 25in.) are used, and strips of ordinary manilla wrapping paper of this width should be provided. The manilla paper should be in one piece about 5 yards long.

Start at one end of the strip of paper by winding it around one of the wooden rollers. The prints should be placed face down on five thin blotters, with five thin blotters on top. These blotters and prints are then placed on top of the strip of manilla paper and rolled in.

Be sure to place the prints in the roll so that the emulsion side is towards the outside of the roll. It is also advisable to place prints in the roll lengthwise, or, in other words, so that the long way of the prints is the same as the long way of the roll.

Do not make rolls too big, or prints on the outside of the roll will not be dried with enough curve. Smaller prints should be placed towards the inside of the roll, and prints of larger size placed towards the outside. This will give them the same relative curve while drying.

Before putting prints in the roll they should be partly dried, as any surplus moisture carried into the roll will lengthen the time required for drying. To accomplish this end, when prints are removed from the wash water they should be stacked and allowed to drain thoroughly. They may then be placed face down on some clean surface until partly dry, or, better still, be placed between blotters for about one hour previous to being rolled up.

Always use perfectly dry blotters when rolling prints up, and it is well to leave prints in the roll over-night so that they will be dried thoroughly before being taken out.

## New Books.

**"CAMERA WORK,"** No. 24.—The latest volume of this sumptuous periodical will not be thought to possess much in the way of new attractions. There are four still-life subjects and three portrait all of them off-met acquaintances of London shows and journal. Needless to say, they are by the Baron De Meyer. There is also literary effort by C. H. Caffin, which may be pronounced apotheosis of Steichen. The book is therefore a little suggestive of "souvenir" of the London Salon. The finest thing in the book W. E. Wilmerding's view called "Over the House-tops, New York." We do not care so much for the laborious imitations of Old Dutch masterpieces, by Guido Rey. They do not bear prolonged examination, their success as imitations being specious to the last degree. A great feature of the letterpress is a series of so-called interviews with several French painters as to the status of photography among the arts. Reading between the lines, it is not difficult to see that the French artists as a whole bear out the truth of the opening line of the article: "Photography has a very undesirable reputation amongst the artists of our times." A majority of the artists appealed to decide frankly that straight and uncontrolled photography is of the most value artistically. It would appear that "Camera Work" has gone a long way from New York to get something nice for itself; but has gone to the wrong shop nevertheless. We think it a bad policy for "Camera Work" to be always either blowing the trumpet of "art" photography or trying to get someone else to blow it. Mr. Caffin's comparisons between painting and photography are futile and wearying because of their antiquity. One who can see nothing but brush-marks in Sargent's portraits, and who pays his hero, Steichen, an alarming number of left-handed compliments, is scarcely well equipped to write upon such a subject.

## New Apparatus, &c.

The "Ensign" Film-Down Washing Tank. Made by Houghton & Co. Ltd., 88 and 89, High Holborn, London, W.C.

Made of stout zinc, this tank is of solid construction. The rack is a novel part of it, the plates being inserted into it in the ordinary

vertical way, but the rack is then placed in the tank so that the film side of the plates is downwards, thus facilitating the removal of the hypo. The rack holds eighteen plates, and costs, in quarter-plate size, 3s.; in 5 by 4, 3s. 6d.; and in half-plate, 4s. 6d.

The "Phaos" Anastigmat. Sold by A. E. Staley and Co., 19, Tavistock Inn, Holborn Circus, E.C.

This is a symmetrical double anastigmat of low price but very good quality. The specimen (of 7in. focal length and aperture  $f/6.8$ ) that we have tested proves to be an excellent lens for half-plate work, as it is free from astigmatism, and gives sharp definition in all parts of the plate at full aperture. The field is very slightly curved at  $f/6.8$ , but this is not a matter of much practical moment. As far as the construction of the lens is concerned, the form of two combinations of three cemented lenses, having no air space, is adopted. The lens combinations are symmetrical, thus giving a single lens—either back or front used alone—of double the focus of the combination.

...and consequently working at an aperture of about  $f/13.5$ , sufficiently fast for all long-distance landscape work. The brilliance of the complete lens is remarkable, and the definition to the margin of the plate for which it is made very critical. The single combination also gives good definition at full aperture. The usefulness of  $f/6.8$  lenses of the double anastigmat type has long been proved. They are well suited to all purposes except the most rapid focal-plane work, and when they can be obtained for the prices quoted by Messrs. Halsey they form excellent bargains. The "Phaos" costs 50s. for a  $4\frac{1}{2}$ in. lens, and 72s. 6d. for a 7in. lens, and these are, perhaps, the two most useful focal lengths.

The "Scientific" Plate Washer. Sold by W. Butcher and Sons, Ltd., Camera House, Farringdon Avenue, London, E.C.

An excellently designed washer, which is certainly a great improvement upon the usual type as regards ensuring a constant change of water in which the plates soak, is shown in the drawing, from which it will be seen that the washer consists of a tank, in which is a division, solid half way from the bottom, and perforated in the upper part. A syphon communicates with the main portion of the tank in

which the plates are placed, and is provided with an air-hole, so that its action, which commences when the water covers the top of the bend, is arrested when the water has fallen to the height of the inverted cone, seen half way up the syphon tube. Thus the action of the washer is always to remove the lower portion of the water standing in the tank, and to replace it quickly by a supply of clean water, reaching it through the perforated division. The washer is therefore most economical of water, and most effective in its treatment of the plates. It is made to take both quarter-plates and half-plates, at a price of 3s. 9d.

## New Materials, &c.

"Ensign" Christmas Mounts. Sold by Houghtons Ltd., 88 and 89, High Holborn, London, W.C.

In varieties not so great as to be bewildering, in sizes and shapes all sufficient for photographers' purposes, and throughout of highly tasteful design and colouring, these "Ensign" cards of Messrs. Houghtons deserve to be successful in exact proportion to the care which has obviously been expended on them. Externally they are of attractive appearance, as are many others. Where they surpass many others is in the equal nicety and fitness of what is not exposed to view. Too often the effect of a colour harmony on the covers of the folding mount is destroyed when the card is opened. In these before us as much pains has been given to producing congruity inside and out as to designing a cover which looks well to begin with. It would be idle to attempt descriptions—soft delicate shades of brown will not admit of them any more than will linen textures or craftsmanship of colouring and embossing. Messrs. Houghtons do their best in a full list, illustrated by numerous half-

tone engravings, two of which we use, while yet advising the reader to pay a visit to High Holborn or his local dealer. The prices of the cards, we would say, range from 1s. per dozen; and we ought not to forget to mention the series of very moderately priced calendars

(with space for insertion of photograph), the utility of which outlasts the bathos of a score of Christmas card mottoes of the "In-friendship's-memory-ever-fond" description. And this reminds us

that Messrs. Houghtons have enforced a commendable *tapu* in regard to effulgent and super-Christmassy mottoes. "Sincere wishes" is about as much as one can hope to get from them for 3d. And enough too, say we.

Dr. Traube's Dye Toners (Permanent) for Lantern-Slides. Sold by John J. Griffin and Sons, Ltd., Kingsway, London, W.C.

A most valuable method has been placed in the hands of the lantern-slide worker by the introduction of the dye method of toning worked out by Dr. Traube, and mentioned over twelve months ago in our pages as the Diachrome process, the name given to it by its inventor. The production of slides of a warm tone is a task which is attended with a good deal of difficulty, and indeed, when slides have to be made by reduction, it is often found impossible to get tones of the same vigour or brilliancy which are produced, by over-exposure and restrained development, when printing by contact. And further, numerous as toning processes are, there are few which give a range of tones in which the image is at once permanent and of the requisite stain-like transparency, which is essential for a good slide. In fact, we doubt if three experienced slide-makers could agree that there was one such process. Therefore, a method which allows of a slide being developed in the first instance to a black tone and being afterwards given one or

other of a selection of warm tones is a method which should highly recommend itself to slide-makers, so long as it does not sacrifice other qualities which go to the making of a fine slide, and we can say in regard to the process now under discussion that it certainly does not.

Our own experience of the method dates back much further than the receipt a day or two ago of the outfit from Messrs. Griffin. We have had the method in use for some considerable time by means of materials specially sent by Dr. Traube, and it may be remembered that we briefly described the principle and practice of the process. However, we may say again that the process consists in the conversion of the silver image into silver iodide, and the subsequent attachment to, or combination with, this latter compound of one or other of a series of special dyes. The process thus very simply consists of bleaching the fixed and well washed slide, rinsing it to rid it of the yellow colour of the bleacher (this takes two or three minutes), and then dyeing it up in the dye solution. This latter operation will take about five minutes, but be the time long or short—and it becomes longer as the dye solution is used—the slide requires no attention, and when fully dyed needs only to be washed in running water for a few minutes; or, if the high-lights are slow in becoming perfectly clear of the dye, in a weak solution of acetic acid.

Messrs. Griffin include in the set of six dyes now being issued a better variety than that which we previously used, and the green tone in particular is a remarkably beautiful and effective colour. In the case of all the colours, the surface appearance of the toned slide or the colour of the solution is no serviceable guide to the tone which the slide will have when projected. A slide-maker would stand aghast at transparencies of the vivid colours of the dyes themselves, but the slides when seen only by transmitted light, e.g., on the screen or when held against one end of a long tube, exhibit none of these vivid garish colours.

The following are the colours (I.) of the dye solutions and (II.) of the slides when viewed by transmitted light—i.e., on the screen or pressed against the end of a long cardboard tube held up to daylight:—

I.	II.
Dark red.	Purplish brown.
Light red.	Warm brown.
Litmus blue.	Grey.
Greenish blue.	Greyish green.
Reddish brown.	Sepia.
Purple.	Purplish.

Messrs. Griffin in their circular of instructions direct the making of the slides on their "gaslight" lantern plates, yet their statement that "other plates may not work satisfactorily" allows us to assume that, on the other hand, they may. And in fact, it should be stated for the benefit of the slide-maker, who does not desire to be restricted to plates of the gaslight variety, but requires to make slides by reduction in the camera, that lantern-plates of the rapid class have been found by ourselves in the case of four or five leading brands to work quite well by the Traube process, and, so far as we could say, irrespective of the developer employed for them.

The outfit for the toning process consists of a tube of bleacher, a bottle of acid, and set of six dyes, and is sold at 4s. 6d. Messrs. Griffin point out, though the outfit may seem at first expensive, it is not really so. The colours should be made into solutions and bottled, and will then keep indefinitely, and will also be useable for an almost unlimited number of slides.

**CRITERION NONSTRESS GASLIGHT PAPER.**—The Birmingham Photographic Company, Criterion Works, Stechford, Birmingham, in sending us a sample of this paper, ask us to confirm their claim for it that it possesses the perfect freedom from abrasion-marking which marks the Criterion "Nonstress" paper of the bromide class. And we can say that in exposing the whole contents of the packet after cutting into small pieces we did not obtain one case of abrasion marks, although the particular sample of paper was employed to test the action of a developer when used to the point of exhaustion, and therefore in many cases the film side of the paper was rubbed against the bottom of the dish. The paper, we may add, tones excellently by the hypo-alum and ordinary sulphide toning processes.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

#### FRIDAY, NOVEMBER 6.

Loughborough Photographic Society. "On the Printing, Developing and Toning of Velox Papers." W. F. Slater.  
Sutton Photographic Club. "Slide Making." J. W. S. Burmester.

### ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held Tuesday, November 3, the president, Mr. J. C. S. Mummery, in the chair.

Mr. H. Lambert exhibited a piece of apparatus consisting of a combination of copying, enlarging, and reducing cameras, which can also be used for other purposes, for example, the photography of small objects such as flowers, scientific specimens, etc. Mr. Lambert explained the points connected with the apparatus, which are fully described in a booklet obtainable from his firm, Messrs. Lambert and Land, 15, Alma Place, Thornbury, Bradford.

Mr. Adolf Abrahams then delivered a lecture on the photography of sport, in the course of which he discussed the making of photographs of sporting events more from the point of view of a sportsman than from that of a photographer, although his numerous lantern

of sporting incidents showed him to have been an industrious photographer in this particular field of work. The lecturer had comparatively little to say on the photographic methods involved in obtaining negatives of extremely rapidly moving objects, but it was there that as regards choice of camera he favoured about equally folding focal-plane instrument of the Goerz Anschutz type and a box. He instanced and illustrated the advantage of using a lens long focus when taking photographs of moving objects of considerable perspective depth, such as a line of runners advancing towards a photographer, or a crew of eight on the river.

**ROYDON CAMERA CLUB.**—The syllabus announced for last week at "Mr. F. W. Bennett, F.R.P.S.," would show his method for developing the sulphide process for producing any tone, from pure black, through brown-black and deep brown, to a warm brown," and he well did the lecturer fulfil his task. It might have been expected that the champion of "control in negative development" might have applied the same principles so far as applicable to the development of bromide papers, but this was not the case, and the strictest adherence to standard and identical conditions was insisted on, and rubbed well in at frequent intervals throughout the evening. At another point which the lecturer laid stress on was that fresh developer should be used for every print, and he stated that if a small quantity was employed for a number of prints in succession it was not possible, by inspection of the finished prints, to say in what order they had been developed, a statement which undoubtedly induces Mr. Bennett to be the happy possessor of a very fine pair of eyes. Diamidophenol was preferred to other developers, and the lecturer drew a distinction between this preparation and amidol, chiefly in favour of the former. The strength recommended was: amidophenol, 6 grains; sodium sulphite, 60 grs.; potass bromide, 10 grs.; water, 4 ozs. The paper should be exposed to suit the developer, which should never be weakened unless it were compulsory to do so. Development itself should be semi-automatic. Turning to after-toning, the lecturer said that differences of exposure undoubtedly affected the final tone. Variations of degree of development, no difference. Reduction with ferricyanide and hypo, either general or local, no difference. It was essential that the prints be thoroughly fixed. If an acid fixing bath (recommended) were used immersion beyond the normal time within reasonable limits did no harm; the reverse might, however, be the case if a plain fixing solution were employed. The standard bleaching bath he had adopted was: Potass ferricyanide, 4 grains; potass bromide, 6 grains; water, 1 oz. The fixing bath: Sodium sulphide, 4 grains to the ounce, a good wash being given between the two. By the addition of small quantities of mercuric chloride to the bleaching bath a large variety of results were obtainable, or a mercury bleach alone could be employed. Whether mercury was used or not the prints might be regarded as permanent in the ordinary sense of the term.

In the discussion which followed Mr. W. H. Smith, referring to an alleged difference between diamidophenol and amidol, said that many chemicals sold as pure, and apparently identical, gave different results. A great deal no doubt depended upon the mechanical methods adopted in their manufacture. Dr. Mees pointed out that there were three diamidophenols possible. Two at least of these might occur in varying proportion in any particular sample, and he accounted for the difference observed. As to the question of "permanency," a bromide print (in which term he did not include light prints) consisted of reduced silver. This was so far satisfactory, but the compounds formed in the after-toning processes were a most weird description. He deprecated in particular the use of mercury. The president, Mr. J. M. Sellors, differed from the lecturer in local reduction not affecting the final print when toned; he had the contrary. Mr. E. A. Salt was unhappy about the definition of "permanency" given. Photographic pictures might be "absolutely" permanent, "practically" permanent, "reasonably" permanent, and "fairly" permanent. He objected to this list being extended, which was sufficient to meet all ordinary requirements. Mr. Bennett, in proposing a vote of thanks, complimented Mr. Bennett on an really excellent and instructive lecture. Personally, he had never used a bromide print in his life, "but one never knew what one might be reduced to." Mr. Bennett, in reply, said that if the last developer were never reduced beyond the bromide stage (a supposition which seems to involve some chemical difficulties) he might consider himself lucky. As to the question of "permanency," he had applied very severe tests, and adhered to the opinion he had expressed.

## Commercial & Legal Intelligence

**CHARGE OF THEFT.**—The further hearing of the case reported in the "B.J." of last week, wherein a photographer named De Jornette Plummer, a coloured man, charged a photographer named Thomas Styles with stealing some 300 negatives and photographs, was concluded at the Hastings Borough Quarter Sessions on October 28. The contention of the defence was that the photos and negatives were practically valueless, that many of them had been given by prosecutor's manageress to Styles as specimens of his own work, and that Plummer had declared he would crush Styles. Without waiting to hear the defence, the jury acquitted accused, a crowded court loudly cheering the decision. The Recorder said it was a trade dispute, and criminal proceedings should never have been instituted. Styles left the court without a stain on his character.

**A FOLKESTONE BANKRUPTCY.**—Benjamin Knight, photographer, Fairlawn, Lyminge, Canterbury, carrying on business at High Street, Folkestone, appeared for his public examination at the Canterbury Bankruptcy Court on Thursday in last week. The summary of accounts filed by the debtor showed liabilities estimated at £219 16s. 9d., and assets returned at £6 18s. 10d. Replying to questions put by the Official Receiver, debtor said he started business in 1905 with a small capital of his own. Subsequently he had businesses at Dover and Folkestone. He gave up the Dover business about twelve months ago, and at that time he owed £100. He attributed his insolvency to bad trade and competition. Debtor's age was twenty-one years and four months.

**ACTION FOR RETURN OF DEPOSIT.**—At the Birmingham Police-court, on Tuesday in last week, A. Marsh, of 190, Monument Road, Birmingham, trading as the Record Photo Printing Company, was summoned that he, being entrusted with £20, the money of Ernest Roy Simms, did unlawfully and fraudulently convert the same to his own use and benefit.

Mr. P. Baker, in opening the case, said that the prosecutor, who lived at 45, Crabtree Road, Brookfields, Birmingham, answered an advertisement which had been inserted by the defendant in an evening paper for a traveller and collector. On applying for the situation the prosecutor was told that he was a very suitable applicant, and would probably get the situation. The wages would be 30s. a week, but he would be required to find £20 as a guarantee of his honesty. On September 9 he parted with his money to the defendant, who said he would either give him a receipt for it, or he could take it on his word as a gentleman that the money should be placed in the bank and returned to him when he left, providing that he had been honest. Prosecutor entered upon the duties, and for two weeks received 30s. a week, but the third week defendant made excuses and only paid him 24s. 6d. The fourth week he was told there was no work and no money, and he had better take a holiday. After that defendant advised him to get another situation, and promised to help him to obtain other employment. Prosecutor applied to the defendant for his £20 deposit to be returned. Some correspondence passed between them, and ultimately defendant wrote saying he could not understand what prosecutor meant by "his deposit," as he had had more than his money's worth by obtaining an insight into the business.

Mr. Simmonds said the defence was that the money was paid as a premium for learning the business.

Prosecutor gave evidence, stating that he left the army in June last, and then had £50 which he had saved. One day the defendant wrote a few things down in a pocket book and gave it to him, saying he would try and teach him the business, and on another occasion he got him to help in the dark-room. He afterwards told him to look out for another situation, and inserted an advertisement in a newspaper recommending him. Afterwards, when prosecutor asked him for the £20 deposit, defendant said he could not give it to him, because he was in a fix, and the money was involved in the business. Up to the present time he had not received any of the money back. He had never entered into any agreement with the defendant to be taught the practical side of the business.

Cross-examined by Mr. Simmonds.—On one occasion the defendant took him to King's Heath when on a photographing expedition. This, however, was not to teach him how to use the camera, but to carry the bag. He admitted that defendant did try to teach him how to put

the plates in the camera once, but denied that he attended at defendant's house four evenings to be taught the practical side of the business. Prosecutor denied that the word premium was ever used in connection with the £20 deposit. He admitted, however, that on two occasions defendant sent him out alone with the camera to try and take a photograph of a road at Edgbaston.

The Deputy-Stipendiary held that this was proof that the prosecutor had received some instruction, otherwise he would not have been entrusted with the camera. The summons would be dismissed.

Mr. Carter (magistrate's clerk) suggested that the defendant might give the prosecutor a portion of his £20 back. It seemed a lot of money to pay for rather perfunctory teaching.

Mr. Simmonds said he would consult his client.

## News and Notes.

**THE AEROGRAPH CO.**—We learn that Mr. A. Aufholz has joined the Aerograph Co. as advertisement manager, to the duties of which position he brings not only a very intimate knowledge of the business, and of the manifold applications of the air-brush method, but also a most successful record as an actual designer and constructor of air-brush instruments, accessories, and installations. One thus acquainted with the business at all points should be a gain to the firm which Mr. A. L. Burdick has so successfully built up on his numerous mechanical inventions connected with the spray method of colouring.

**MESSRS. F. E. JONES AND CO.** notify us that they have unfortunately had their show-rooms and offices burnt out. A wooden beam caught fire from an overheated stove, and, having smouldered all night, broke into flame early on Thursday morning last week. Messrs. Jones are, however, carrying on business in temporary offices at the same address, 22, Gray's Inn Road, Holborn, W.C.

**THE FORREST AEROPLANE.**—According to a paragraph in the "Edinburgh Evening News," Mr. George Forrest, a photographer, of Brechin, is the inventor of a flying machine, a trial of which he hopes to make on an early date.

**NORTHERN PHOTOGRAPHIC EXHIBITION.**—With the close of the "Royal" and "Salon" we would draw our readers' attention to this important exhibition, which has now taken a high place in pictorial photography, and can certainly be well recognised as the most important in the provinces. It is run on broad progressive principles, and is well worthy of support by exhibitors. It will be remembered that this series of exhibitions are held alternately in Manchester and Liverpool, the one held last year in the latter town having been the greatest success of the series. The forthcoming exhibition will be held in Manchester, January 6 to 27, three fine rooms being placed at the disposal of the Manchester Amateur Photographic Society for this purpose. Pictorial photography, lantern slides, and colour work are to be the leading features, and already promises have been received from most of the leading workers in this country, and a good measure of support is expected from Russia, India, Italy, Germany, Austria, France, South Africa, and America.

The President of the Royal Photographic Society, Mr. J. C. S. Mummery, will act as judge, and all work hung will pass before him.

Fifteen handsome plaques, about 9x5, will be placed in his hands for awards. The plaque has been specially designed and modelled at the Manchester School of Art, and will be reproduced by the "Kupron" Company. Those of our readers who have not yet received entry forms should obtain one from the Hon. Sec., Mr. S. L. Coulthurst, Broad Oak Road, Worsley, Manchester. Special attention is to be given to Autochrome and all forms of colour photography, and to this we draw the special attention of our readers. A specially fine catalogue, on the model of past years, is being prepared, and we are informed that it will contain upwards of 35 full-page illustrations, the size of page being 10 x 8. Lantern lectures on photographic subjects have been arranged for each of the nineteen evenings the exhibition is open.

## Correspondence.

- \**Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*
- \**We do not undertake responsibility for the opinions expressed in our correspondents.*

### LANTERN SLIDES BY REVERSAL.

To the Editors.

Gentlemen,—Will you kindly permit me, through your columns, to thank Mr. Fenske for the suggestion made in his letter of last week's issue to the effect that it would be advisable to expose lantern glass slide towards the lens, in the process of reversal described in the "B.J." for October 23.

I will certainly give the suggestion a trial when opportunity affords, though I must confess that neither does the theory nor the results of the *rationale* of my process encourage me in anticipating better results from its adoption, nor do I follow Mr. Fenske's argument on which he bases his suggestion—viz., that if the image has been through the glass the reversal is easier and more complete, the image being on the top of the film; whereas, in ordinary exposure, film to lens, the image is at the bottom, that is, near the glass.

Surely the locations of the images in the two methods of exposure are just the very opposite to those here alleged.

I would submit that the reason for the superior results Mr. Fenske obtained when using a screen may have been due solely to the fact that the actual exposure with the screen was not exactly equivalent to the exposure without it, and just happened to be better adapted to the reversal process, the success of which depends so largely on the exact amount of exposure (as measured by the density of the negative image) that the plate receives.

I have on several occasions experimented on the method of reversal referred to in the last paragraph of Mr. Fenske's letter—a method which dates back to the collodion era of photography, and which was first described by Sebatier. But I found the method so uneconomical in operation and generally so unsatisfactory in its results that I abandoned all hope of its successful adaptation to the production of passable lantern slides.—Yours faithfully,

November 2, 1908.

DOUGLAS CARNE

## Answers to Correspondents.

- \**All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C."* Inattention to this ensures delay.
- \**Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*
- \**Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington Street, Strand, London, W.C.*
- \**For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24 Wellington Street, Strand, will undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, and two unmounted copies of each photograph must be sent with the fee.*

### PHOTOGRAPHS REGISTERED:—

- Mrs. M. Egerton, Cheynton Cottage, Alresford, Hants. Photograph of the interior of the Tichborne Dole.
- Mrs. M. Grainger, High Street, Heanor, Derbyshire. Photograph of Becket Square, Heanor, Derbyshire, Queen's Jubilee, 1887.
- W. E. Turtin, 59, Blacker Road, Birkby, Huddersfield. Photographs of the Wagstaff, Wm. Kitchen, and Percy Holroyd, all Northern Union Football Players.
- L. Roberts, 140, Fairbridge Road, Upper Holloway, London, N. Photograph of the Rev. T. H. Arber, M.A.; Rev. W. Stephens Muntz, B.D., LL.D., Rev. A. W. Couch, B.A.
- W. H. Warburton, Harris Promenade, Douglas, Isle-of-Man. Photograph of the Manz House of Keys (the House in Session).
- Cristabel O'Shea, 7, Lewes Crescent, Brighton. Three Photographs of the Summers, Bower; three photographs of J. W. Summers and H. Paul, Esq.

**ARTIFICIAL LIGHT.**—Of the two we should choose incandescent which is capable of good work for heads and busts, but i

ual to the work of an arc lamp. Several incandescent lamps supplied by the Tress Co.

**OUR PHOTOGRAPHY.**—1. Could you oblige me by giving me the address of the Hoechst Dye Works mentioned by E. J. Wall in his book on Colour Photography, or their agents in this country, they have such? 2. Also can you tell me where I can get Dr. H. Smith's, of Zurich, "Uto" paper, and the Warner-Powrie plates? 3. Regarding the paragraph in the correspondence in our October "Colour Supplement," re bathing Autochrome plates in potass. metabisulphite solution, and then developing by yellow light, can you tell me if this can be done with Panchromatic plates (Wratten and Wainwright's)? I have tried it and the plates fogged, but this may have been owing to some (unknown to me) defective condition.—ALEX. HUTTON.

1. Meister Lucius and Brüning, Hoechst, Frankfort-on-Maine, or Ernst Bros., 17, Philip Lane, E.C. 2. Neither are at present obtainable, so far as our information goes. 3. We have no reason for assuming that it would affect all plates similarly, in fact, experiences are discordant as to its effect with Autochromes.

**RIGHT.**—I recently copyrighted a negative, describing it as a "photographic negative"; part of the description was scratched out, the "ic" of photographic, and the word "negative," and the form was returned with instruction to describe of what the photograph was I had sent a print. Does the copyrighting of a photograph secure the copyright in the negative?—S. H. C.

If you turn to the "Copyright Act" on page 906 of the "Almanac" you will see that the wording expressly mentions the negative. Protection is given to the "photograph and the negative thereof." It is not usual to enter the subject as a negative when registering.

**PAPER.**—3. Are self-toning C. C. papers largely used by professionals of repute? 4. Which do you consider the best camera for Press work? I have a half-plate focal-plane reflex, but it is rather a heavy thing to take about.—X. Y. Z.

Neither are quite as permanent as collodion paper toned with gold bath followed by platinum. 3. It is not easy to say, but we should judge that the most general method is the gold-toning, although the use of self-toning papers is undoubtedly on the increase. 4. It is an excellent camera for a large portion of Press work, and your particular make of instrument is almost always to be seen at Press functions. For sport and general photography of rapidly moving objects a camera of the Leica-Anschutz type is more generally employed.

**(Rochdale).**—You must prove damages. In the case of infringement after registration you can sue for penalties, in which case you have only to prove the infringement. See the Copyright Act, page 909 of the "Almanac."

**GUILD (Manitoba).**—1. The difference lies in the mechanical construction (automatic) of the arcs. The lamp is quite different in construction from the usual pattern of open arc. 2. Both types of arc are largely used here, one as much as the other should say. 3. The colours used are the secret of the manufacturers. Up to now they have the reputation of permanency.

**Q.**—Try a warm solution of oxalic acid.

**ON NEGATIVE.**—Could you kindly let me know how the stains on the enclosed negative? It came when developing (metol-roquinone), etc. It was near no hypo, and I am very careful to touch the film when changing. As I take a good few at a time I should be glad if you will enlighten me on the matter. I say I have had three like it, and the stains are all alike, in about the same place.—T. D. S.

The marks are all alike and in the same place it would appear either the dark slide is at fault or else the packer or maker of the plates. If all the plates were exposed in the same slide we should suspect that, but if this was not the case we should send negatives to manufacturers and ask their opinion. The appearance suggests a grease stain on the plate, but we cannot suggest any special cause.

**PRINTS.**—We have just had the enclosed print returned to a customer, and should be glad to know your opinion as to the cause of the fading. The print is about fifteen months old — sulpho-cyanide bath. It was washed with a batch

the remainder of which are all right. You can see the class of board it is mounted on.—STICKYBACK.

The lines visible on the print suggest that this particular one has had less perfect washing than the others in the same batch, owing to prints sticking together in the wash water. At the same time the mount looks doubtful, and we suspect it is not of very pure material. You do not say what mountant was used. This, of course, might be responsible for the effect, and possibly the lines simply show brush-marks. We should test the mount for hypo, and if it passes the test the cause must obviously be one of the other two things. If the print was not quite perfectly washed and the mountant was slightly acid, the effect would be produced very readily.

J. C. W.—We doubt if anything will now move this stain, but you might try a bath of alum and citric acid. If this fails, the only remedy we can suggest is to bleach the image and redevelop. A suitable bleacher would be potassium bichromate, 10 grains; hydrochloric acid, 20 minims; water, 1 oz.

**GROUND GLASS VARNISH.**—Please give me formula for ground glass varnish, to stand heat, as on incandescent electric globes.—F. HARTLEY.

We fear the ordinary sandarac varnish would be useless. The lamps are usually matted, we believe, by a mechanical sand-blast or similar method.

**AUTOCHROMES.**—(1) I always place Autochromes before developing for three minutes in a 3 per cent. solution of formalin to prevent frilling. A letter in the "B.J." recommended placing the Autochrome in a 3 per cent. solution of potassium metabisulphite for thirty seconds in order to destroy the colour-sensitiveness, and thus enable one to develop in a bright yellow light. Can I combine these two operations without injury to the plate, and use a solution composed of formalin 3 parts, water 100 parts, and potassium metabisulphite 3 parts? (2) With the pyro I always use sodium bisulphite as a preservative, and I also use this chemical for clearing off stain after the acid permanganate. Will potassium metabisulphite be equally effective in both cases?—E. Y. E. N.

(1) We are doubtful as to the effect of combining formalin with an acid sulphite. It is possible that the acid would prevent the hardening effect of the formalin. You might use formalin alone and follow with the pyro acid sulphite solution, for, say, twenty seconds. Then pour off the pyro solution, add the ammonia to it, and re-flood the plate. We are doubtful as to the safety of the "bright yellow light." Why not use Lumière's special green light? The materials are cheap and the light very pleasant to work by.

(2) Metabisulphite should be quite as effective, but it cannot be made up in such a strong solution, so the soda-bisulphite is more convenient.

**LENS FOR GROUPS.**—In "Answers to Correspondents" of April 17 last, page 316, I note your advice to "Lens Query" is to get a "Stigmatic portrait lens working at  $f/4$  for groups." This is what I want, as my 8 $\frac{1}{2}$ in. focus portrait lens (first-class English make) has not sufficient depth of focus or definition (as I don't suppose any portrait lens has) for groups of four, two sitting and two standing behind, unless I stop it down to  $f/6$ . This is too slow for gaslight work. If I am right in thinking that it is a Stigmatic portrait lens you advise for groups, please let me know, through your journal, where I can get one. Dallmeyer, Ross, etc., I have no doubt make them, but their prices are too high for my class of work.—P. STEWART.

The Stigmatic lens is only made by Dallmeyer's. But you must keep it in mind that no lens, whatever its make, with a large aperture will give much "depth of focus" unless it is stopped down. The portrait ( $f/4$ ) Stigmatic, however, is fitted so that the focus can be diffused, and that gives more-apparent depth.

**RESTORING PAINTINGS.**—I should feel obliged if you could kindly give me formula for cleaning and restoring oil paintings. I am a photographer and oil artist, and am often asked to do this class of work. I have on hand now a large-size painting (size about 50 x 30), which I should say is over 100 years old, and is quite black with age, and almost invisible, and cannot repaint without cleaning, as I have done in previous cases.—OIL PAINTING.

There is no formula for this kind of work; it is a business that

requires considerable knack and experience. In the first place the old varnish has to be removed, and that is done by rubbing it off with the finger, which is a very tedious work, and requires considerable time and patience. It is not within our province to give detailed instructions for restoring oil paintings. We should advise you to get the "Carver and Gilder's Guide," published by Kent and Co., Paternoster Row, E.C., if you are going to attempt to do the work yourself; or, better still, if the picture is a valuable one, place it in the hands of a professional picture restorer.

**LENS QUERY.**—I have a lens and engraved on same is "P.A.C.S.A., 43, Charterhouse Square, E.C.,  $8\frac{1}{2} \times 6\frac{1}{2}$ , wide angle, 740." Can you tell me through the medium of your journal value of same second-hand?—ALBERT DAY.

P.A.C.S.A. means the Photographic Artists' Co-operative Supply Association, a concern that became defunct many years ago. The lens has practically no market value.

**IVORY FOR MINIATURES.**—Can you tell us cheapest houses supplying bleached ivory for miniature work?—DISCLES.

All artists' colourmen supply ivory for miniature painting, but we cannot say which of them supply it the cheapest. Better procure one or two price lists and compare.

**JACKS BROS.**—We would suggest that you remove the partition between the chimney breast and the south-east side. This will give you a good length. The fact that you would have to work the studio a little crosswise is of no moment whatever. As the roof is so low the glass had better be carried up about half way, where the tiles now are, and commenced 3ft. or 3ft. 6in. from the floor. As you say that the south-west side is blocked by high buildings there is no need for glass on that side.

**CARBON PRINTS, ETC.**—(1) Some time ago you published particulars for carbon prints on vellum. Will you please give dates of your journal in which they appeared? (2) I have been trying to block out backgrounds, but cannot get a good clean outline round figures for sketching fresh backgrounds. Can you tell me how this is best done? Is a pen used or brush, and shall I work on film? I am told it is done by means of a transparency (carbon) and then printed by single transfer. Your valuable help will be much appreciated.—OTALP.

(1) The article appeared in the "Journal" for January 17 of this year. (2) The blocking out is generally done with a brush, and on the film side of the negative. If you do not get a clear outline it is because you do not do the work neatly enough. Photopake, as sold by the Vanguard Company, is a good medium to use.

**DUN-DOWN.**—Name and address, not necessarily for publication, should accompany inquiries to be answered in this column.

**PRICES.**—I have photographed three carved mantelpieces on whet-plates, charging 5s. for each exposure and one print of each, receiving an additional order of six copies from each unmounted at 2s. each. The customer now refuses payment on the ground of very excessive price, offering me 7d. only for each copy, quoting from a catalogue of which I have no knowledge, and further demands my negatives without additional payment. Would you kindly answer the following queries through your esteemed "Answers to Correspondents" column. 1. Is 5s. for one exposure and one print excessive? 2. Is 2s. for each additional copy excessive? 3. Am I obliged to give up my negatives without further payment?—J. A. McPHAIL.

1. A moderate price, certainly, for good work. 2. It depends on the class of work; they should be first-rate prints at this price. 3. You cannot be compelled to give up the negative under any circumstances, unless you specially quoted for supplying them to the customer.

**PRESERVING NEGATIVES.**—I should be glad to hear what you think the best way to preserve the gelatine negatives of to-day. I have tried several methods, but none seem quite satisfactory. They do not keep anyhow with me so well as the old collodion ones; varnished or not varnished they deteriorate.—CLIMAX.

The best protection we can suggest is a celluloid varnish such as that of the Vanguard Co.

**A CASE OF DELIVERY.**—I had occasion to take a series of twelve views for a country dealer from which he gave me an order for a great gross. I have sent him to date a consignment of 56 dozen.

He now writes saying, "Please stop printing for a time as d has fallen off." What he has had he has paid for, but I like to know if I can finish off his order and send in for b of account, as I have put all other work on one side for I do not want to have this one order hanging on indefinitely it now appears likely to do. I had the order verbally.—

PRINTER.

So far as we can judge you cannot force acceptance remainder in view of your acceptance of payment for part order. It seems to us that such partial payment entitles you to ask for delivery in batches.

**BACKGROUNDS.**—Kindly say (1) whether all the necessary tints white to black can be produced by the artists' powdered colour mentioned a few weeks back in your "Ex-Cathedra." Where can I get suitable copies for backgrounds? Those advertisement pages of the "Almanac" or "Journal" may copyright, whilst the natural pictures produced by the lack that good composition so necessary in artistic work. There on the market any fixed focus cameras having a working aperture than  $f/8$ ?—ARTIST.

(1) Apply to Marion and Co., 22 and 23, Soho Square, L.W., or Reeves and Co., Farringdon Avenue, E.C. (2) We have none, except those in paintings, etc., copyright in which has expired. (3) Not that we know of, nor is there likely to be seeing that depth at  $f/7$  and larger is so small. See the title of the "Almanac," p. 960.

**GEO. COLLINS.**—Of the two materials sent, the darker one is the best for your aspect of studio. But the fabric is a little thin though the colour is right enough. We should think those who supplied you with the patterns could procure thicker material, if they have it not in stock. (2) In your spring rollers for the roof would be the more convenient and for the sides curtains running on rods or wires.

**ALBUMEN PAPER.**—I wanted a little albumen paper to see and I ordered some from our local chemist and photographer, and he obtained it for me. When I opened the paper was met with a most offensive smell; in fact, a "fair stink" that the case with this paper?—NOVICE.

Some albumen papers have a very offensive odour, while others have not. The odour is due to the paper being prepared from decomposed albumen, but that does not seem to interfere with working.

**THE LATE RICHARD WICKS.**—Many of our readers will remember the death of Mr. Richard Wicks (of the Brighton Photographic Company), who was well known among professional photographers. The deceased was 71 years of age. His experience of photography dated back to the Daguerreotype era, and he practised the art in the West Indies in 1860. His knowledge of the older photographic processes was very extensive. He died of a paralytic stroke only four days' illness, and was buried on the 29th ult. at Brighton. The deceased gentleman had been in business in Brighton for many years, and was greatly respected in the town.

**NOTICE TO ADVERTISERS.**—Blocks and copy are received for the approval of the Publishers, and advertisements are accepted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

"The British Journal Almanac."—Our publishers desire to advise readers that nearly the whole edition is exhausted, and that therefore orders for the "Almanac" should be put in without delay.

An exhibition of the work of Mr. William Crooke is now being held by the Edinburgh Photographic Society. (P. 872.)

An American worker has advised a method of local development for use in studio work. (P. 865.)

Some practical points in the cutting up of prints and mounts and the rapid packing of photographs are mentioned on page 862.

Advertisement Photography.—One or two notes on this branch of professional work are given by an American photo-engraver. (P. 870.)

Test Negatives.—A further article on the method of making multiple-negative test-plate by means of cinematograph film appears on page 863, and describes the method of preparing a negative in such a form that it can be used with any series of separated strips.

Screen-plates by a ceramic process and by a selected dye process are among the patents of the week. (P. 873.)

Mr. J. F. Duthie has contributed his experience in the photography of rapidly moving objects. (P. 871.)

It is announced that "Australian Kodak, Limited," under the direction of Messrs. Baker and Rouse, will manufacture Kodaks, and Kodak roll-film, plates, and paper, in Australia. (P. 872.)

Testing Shutter Speeds.—Mr. Douglas Carnegie describes a simple method of testing the speed of a shutter by photographing a falling dy. (P. 864.)

Dr. W. J. Russell, in continuance of his researches on the action of photographic bodies on the photographic plate in the dark, has examined the action of resin and similar substances, and has discovered a difference in the action of coals on a dry-plate which would appear to have some value as a means of distinguishing between different classes of coal. (P. 866.)

## EX CATHEDRA.

### Lectures at the Society of Arts.

The arrangements for the session of lectures upon scientific and industrial subjects at the Royal Society of Arts are now published, and are found to contain several fixtures of photographic interest. On December 9, Messrs. G. Albert Smith and Charles Urban are to read a paper on "Cinematography in Natural Colours," which will doubtless be accompanied by a demonstration of the remarkable results obtained. Although these latter have been shown semi-privately, they have not yet been brought before a society, and the paper should therefore be of exceptional interest. Among the Cantor series of lectures, that on "Methods of Artificial Illumination," by Leon Gaster, should be of importance to photographers, and we may therefore say that, though the proceedings of the Royal Society of Arts are officially confined to members and their friends, the courtesy of admission to a particular lecture is usually granted on application to the secretary, at John Street, Adelphi, London, W.C.

\* \* \*

### Formula for Profit and Loss.

We are afraid we do not know enough of the forms which German humour may take to decide whether a recently reported address by Dr. Miethe on the application of algebra to the supervision of business accounts is to be taken in earnest or as a piece of mock seriousness. In it is given the formula:—

$$\sqrt{a/b}(A + c/d \cdot M + C),$$

in which, so we are told, the symbols must have certain values in the case of a business which is prosperous, others in the case of one being run at a loss. We doubt if any material consolation in regard to a concern which is, say, £600 on the wrong side is derivable from a confirmation of this fact by the formula, or whether a pressing creditor, by a Germanised version of the methods of Mr. Harold Skimpole, could be convinced that, according to the formula, it should be the easiest thing in the world for him to collect his account, that virtually the money is in his hands, and in that case why prolong a distressing interview?

\* \* \*

### Concentrated Developers.

Many of our correspondents express a preference for strong stock solutions of developers, and sometimes we have to point out that the solutions cannot be as concentrated as they wish, owing to the slight solubility of some of the ingredients. As most photographers know, Mr. Watkins has recently introduced a very excellent developer in such a concentrated form that some of the ingredients are not dissolved. By inverting the bottle three times the solid matter is brought

B

into a state of suspension, in which condition the required quantity can be measured out. When diluted to a working strength, the undissolved particles quickly go into solution, and so we get the developer into working order. Such a concentrated preparation as this cannot properly be described as a solution, but it is a very convenient substitute for one. It is far easier to measure out the solid when suspended in water than it is to weigh it in the dry state, and there is no reason why the idea should not be more often adopted. It is not applicable to a good many substances that form large crystals, but it is to many developers that are not very readily soluble. It is, however, very necessary to be sure that the suspended matter is quite dissolved before applying the developer to the plate, otherwise spots will most certainly appear on the film. For this reason such a developer should be mixed about ten minutes before use, and it should be carefully inspected in a good light. Solution can be hastened by pouring the solution backwards and forwards from one measure to another, and the safest course is to do this for half a dozen times, and then wait ten minutes. The advantage of a clean, perfect solution is, however, so great, that a little trouble is worth taking. It is certainly always worth while turning up the light to examine the solution before actually starting on development, and, in the case of time development as distinguished from the factorial system, there is no objection to occasional full light in the dark-room.

\* \* \*

#### **Dissolving Sulphite.**

Many workers make a great fuss about the preparation of a fresh solution of sodium sulphite on the ground that it does not dissolve readily, and to save trouble they often use stale solution, even though fully aware that fresh ones are the most reliable. In point of fact, sulphite dissolves very readily indeed, and when it fails to do so it is more often than not due to the use of hot water. It is much less soluble in boiling water than in water at a much lower temperature, and it dissolves with the greatest rapidity in water at about 90 deg. F. If put in a bottle with water at this temperature and well shaken, the rate at which the crystals disappear will probably be a surprise to those who quite unconsciously have always hindered its solution by the use of hot water. If required to keep the solution in cold weather, it is generally found that a strong solution that has once been heated up to boiling point will not crystallise out so readily as one that has never been heated, but the heat should not be applied until after solution is complete. The attempt to boil the liquid while crystals remain in it simply delays solution for a very long time.

#### **THE USES OF A PAPER-CUTTER FOR PACKING AND OTHER PURPOSES.**

We recently noticed in the "Answers" column a query for a machine to cut a number of prints and attached dry-mounting tissues together. There are various machines to cut quantities of paper in this fashion, but for the particular purpose we can scarcely think that the result would be quite satisfactory. For instance, the head on a dozen similar untrimmed prints will never be in exactly the same position in each one, so that were they trimmed in a pile the position of the head or other feature would in some be incorrect. This defect would be the more apparent in a photograph containing perpendiculars, such as architectural work, street scenes, or studio work with a panelled background or one containing a pillar. Although possessing drawbacks for wholesale trimming of prints the recent acquisition of a cutting machine leads us to recommend a similar purchase to a business of any size. A great saving of time will be effected in the smallest place, whilst its use in a large business would greatly simplify and quicken certain operations. The work the machine will do can be equally well done by the local printer, but the time and trouble taken to cart material off the premises, and the convenience of having the machine always ready to hand, make the purchase of a cutter the most economical policy.

The most perfect machines, and those with the greatest capacity, are the various types of the printing trade guillotine, varying from the lever press of twelve-inch cut and costing about six pounds, to the elaborate electrically-worked instruments running into hundreds. With a machine of less than twenty-six inch cut, however, one will be constantly handicapped, and seeing that a proper guillotine in this size would be of an excessive price for a photographer, and the chief advantage of these machines—viz. the great thickness they can cut at one stroke—is not of much advantage to us, we have obtained an extra large specimen of blunt knife print-trimmer that costs three pounds odd only and gives a twenty-six inch cut. Similar machines are listed by all the big dealers.

For accuracy and ease in working it is advisable to fix the machine with a fence that will move absolutely parallel to the blade and can be fixed rigidly in any position. This fence not only renders it easy to make any number of cuts of exactly the same width (determined by the distance of fence from knife), but it also ensures perfect correctness of right-angles—a most important matter when cutting mounts or tints. The beds of these machines are carefully ruled with squares, but it is much simpler to be able to push the work up to the fence. This addition can be made in wood by the joiner and should not cost more

#### **THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1909.**

Edited by GEORGE E. BROWN, F.I.C.

THE forty-eighth annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published on December 1. This year's ALMANAC reached a total of over 1,000 pages, and the entire edition of 25,000 copies was sold out immediately. Of no other photographic book ever issued can two such unique facts be recorded. The edition for 1909 will also consist of 25,000 copies.

The editorial article will deal very completely with the important subject of

#### **REFLEX CAMERAS,**

and the systematic review of the work of the year under the title "Epitome of Progress" will be a strong feature of the volume.

The lines followed in the previous editions of the

ALMANAC will be maintained in general, but in a number of particulars the arrangement of the volume for 1909 will be modified to make it more than ever the book of universal photographic reference.

The ALMANAC for 1909 will appeal to photographers all the world over as a daily reference guide in practical work. The standard matter and formulæ will be revised and added to where necessary, and, wherever practicable, new features of an informative nature will be added.

**NOTICE—IMPORTANT.**—Our publishers ask us to inform agents that the issue of 25,000 copies is now almost booked and, as a second edition will not be printed, those news agents and dealers who have not yet sent in their orders are advised to do so without delay.

an half-a-sovereign. If the man does not understand, advise sending him to see the printer's machine, and he will grasp the idea at once. It may assist the reader if we enumerate a few of the uses to which the machine can be put, though its use and convenience should be fairly obvious. For trimming single prints larger than whole-plate size it is handier than keeping large shapes that can break, whilst the thickness of the paper makes no reference to the cleanness of cut. For cutting up sensitized paper in quantities up to two quires it is far quicker than with the knife or tearing. The clean edge is preferable to the rough one if the paper is cut very close to the finished size, whilst there is no danger of small bits getting between negative and paper. Nowadays it is not advisable to stock many large 12 x 10 or 15 x 12 prints, since taste with regard to colour varies so much. The mount paper of selected tint on to a mounting board required, trimming afterwards. Photographers who will find the machine a saver of time and energy, use the thickest card is cut perfectly clean, with no effort, a tenth of the time taken to use the mount-cutting knife. For folders, which are blocked with name and address in hand-press, the saving is equally great, it being most impossible to carry a full stock of printed folders of the innumerable sizes and colours from midget to 12 x 10 both upright and view way. In the case of the favourite cabinet size, 10 x 8 outside size, which cuts six to the sheet, one would get a lot of waste or odd sizes if all the prints were cut from one sheet and the folders from the other. With the machine one cuts an equal number of prints and folders to match at the same time, two mounts in a 3 in. x 8 in. and two folders 16½ in. x 10½ in., which just makes the full sheet.

Whilst the machine is most indispensable for trimming prints of all descriptions, it will be found to wonderfully simplify packing, at present a troublesome matter that gets little attention from photographers. Packing seems simple, but as usually carried out, especially for the post, is lengthy and frequently not too neat. We think that a great impression conveyed to the recipient of the parcel comes to no slight degree their appreciation of the contents. The client would not admit this influence, probably does not know it, but that it exists is recognised and advantage taken of it by all the big retailers who put up their prints ready packed. The photographs cost money, and they should be wrapped up with all the care the jeweller exercises with his goods, so as to convey an idea of value. We think it advisable to place prints complete in their folders, first in a wrapper of good paper fixed with sealing wax impressed with an initial, then either between corrugated paper, if for stiff mounts, or between stout strawboard if paper ones, enclosed in the outer wrapper and tie. All this sounds tedious, but if packing arrangements are made in a methodical fashion it is as easy to do well as badly.

In a business such as a photographer's, where the outside dimensions of various stock sizes are similar, it is easy to systematise the matter. If your mounts are not all of equal area in the respective sizes, you should take an opportunity of bringing them into line. It simplifies matters from beginning to end to have all mounts, all papers, all tissues of the same size. We may name as most economical carte mount size 6 x 4, cabinet 10 x 6, whole plate 12 x 10. For these sizes we cut a number of sheets of strawboard and corrugated paper to dimensions very slightly larger and keep on special shelves for each size. The white paper and the brown are also cut to correct sizes for use, the machine getting through sheets of brown at one cut. With everything ready stacked in their positions and a good string-holder, it becomes almost a pleasure to pack after long association

with the untidy time and space wasting muddle to be noticed in many photographic establishments. Sealing was rather a nuisance until we obtained one of the small Bunsen burners, price one shilling, used by chemists, and had it fixed in a convenient position on the bench. With a method of this sort, almost as quick and much cheaper than the old book-form wrapper, it becomes a good business policy to offer on one's circulars to pack individual prints for customers. This offer will be eagerly accepted, especially at Christmas, and no doubt would bring extra business. Many people who would otherwise purchase photographs fight shy of the labour entailed in their distribution. That this is natural must be admitted, for troublesome as it is to us, how much more so must it be to the ordinary household that always lacks such necessities as card, paper, string, and labels. With regard to these latter, to save trouble, avoid mistakes, and secure an extra advertisement, the client should be supplied with your stick-on labels, upon which to write the necessary name and address.

### CELLULOSE TEST NEGATIVES.

In our issue for August 21 we pointed out the usefulness of test plates made up by mounting short lengths of cinematograph films on a glass plate, and varying the opacities of each picture by masks of tracing-paper or papier minéral. When made up in this way it is obvious that the paper series of opacities must lie between the film images and the glass, therefore if different test plates with varying scales are required each one must be made complete in itself. It is far more convenient to have the series of small pictures mounted on celluloid, for then different series of paper gradations can be used in conjunction with the same set of film pictures. After a little experimenting and a few failures we have found a very satisfactory and easy way of mounting the films on celluloid, and a description of it may be useful. If we fix the cinematograph films across the length of the plate we can get three strips side by side, and fifteen pictures in all on a quarter-plate. By mounting the strips across the width of a plate we can, however, get sixteen pictures in the same space, so this is the method we have adopted. First cut four strips of film, each containing six pictures. From two of these strips trim off the perforations on both sides, and from one of the others trim off the left-hand margin, and from the last strip the right-hand one. The four strips when placed side by side will now measure just about 4½ inches. The total length of film used will be about 18 inches, and if the film available has been kept for an hour or so rolled up with the gelatine coating outside there will be little or no trouble from curling. The two strips that have been trimmed on one side only will be the outer strips on the finished plate, and the perforated edges will come at the margins.

Next, take a piece of stiff card and lay one of the outside strips face down upon it, holding it down with a quarter-plate cutting shape so that the three central pictures are covered by the glass. Lift up the ends, which will each contain one picture, brush a little cement on the face of each, and also on the card underneath, and then press them down firmly. Then take one of the centre-trimmed strips of film, slip it face down under the cutting shape, and arrange it edge to edge against the previous strip, so that the pictures are in alignment. Cement the ends down as before, and then proceed in exactly the same way with the third and fourth strips. The trimming of the strips should have been effected with a knife and straight-edge. If carelessly cut with scissors the edges will not lie close together, and close joints are most desirable to prevent cement oozing through to the front in the

after operations. The four strips are now face down and side by side, attached by their ends to the card, and held down flat in the centre by the weight of the cutting shape. To prevent them from rising when the shape is removed it is as well to put a piece of lantern binding-strip along each end, half on the card and half on the celluloid. The cement takes some little time to set, and the films will rise if there is any curling tendency left in them. The cement referred to is that described in our former article—gelatine dissolved in acetic acid. To make a solution the bottle must be placed in boiling water. The bottle can be about one-third filled with strong acetic acid, and then gelatine is added until the consistency is about that of glycerine. Powdered soup gelatine is most convenient in use. Heat is applied until solution is complete, but after that the cement can be used cold.

When we are sure that the film strips are firmly secured at their ends to the card, we remove the glass shape and join the strips together with four-inch lengths of lantern-slide binding, cut down to about 3-16 of an inch in width, and moistened with cement. Gum cannot be relied upon for this purpose, and even the fish-glue variety is hardly safe. We always use fish-glued strips moistened with cement. Wide strips can be used at the extreme sides over the perforations and overlapping on to the cardboard, and similar strips can be used across these to form the other boundaries to the sixteen pictures utilised. These latter strips will overlap the pictures at top or bottom by

about  $\frac{1}{8}$  of an inch, and they must be cut so that double thicknesses of paper occur at the corners.

All that now remains to be done is to paint a line cement down each of the paper strips, and then quickly down a piece of  $4\frac{1}{4}$  in. x  $3\frac{1}{4}$  in. celluloid over the whole as to just cover the sixteen pictures and their margins. A cleaned quarter-plate "cut film" is just right for the purpose. The whole is then left under pressure for three or four hours, and finally a sharp knife is run round the edges of the celluloid cover, and the completed negative lifted up.

As an extra refinement the pictures may be separated horizontally by strips of black binding paper about 3-32 of an inch wide. These are cut about five inches long, cemented down right across the whole length of the plate. Two or three minutes after they have been rubbed down the short pieces that overlap the vertical strips are removed with a knife on either side of the verticals, the extra thickness of paper is picked off. This is necessary, otherwise the celluloid cover which is put on will not lie flat.

We can now build up suitable graduated screens, tissue paper, etc., either upon glass plates or celluloid, and our test film can be backed up with any one of these screens that is most suited to any particular purpose. Numbers are wanted on the test pictures they can be easily written in Indian ink on the film itself. They should be written backwards for preference.

## A NOTE ON SHUTTER SPEEDS.

FROM the review of Professor Worthington's fascinating book, "A Study of Splashes," in the "B.J." for September 11, the following paragraph is quoted: "The catapult method of releasing the falling ball and the device for making the exposure at a pre-determined time are both suggestive of ways of arranging shutter-testing apparatus."

Some years ago I employed, on the first camera I ever possessed, a method of shutter-testing in which there was a "device for making the exposure at a predetermined time" similar in principle to that adopted by Professor Worthington. The accompanying rough sketch (Fig. 1) explains the principle

Fig. 1.

of the method. C is the hand camera, the shutter of which could only be actuated by pneumatic ball. A piece of stout rubber tubing was attached to the nipple S at one end, and to a bottle, D, containing mercury, at the other end. On its way from S to D it was gripped air-tight in a simple form of mouse-trap, MT, which was much in vogue some years ago, and was vended at twopence or so, under the name of "the break-back trap."

By means of the rubber hand pump IP a predetermined pressure sufficiently great to actuate the release mechanism of shutter was established in the bottle D, the pressure being indicated on a gauge D. (I remember being rather surprised at the magnitude of the pressure necessary.) A battery, E, of Leclanché cells sent a current round the circuit bKEE<sup>1</sup> when the key K was closed. E and E<sup>1</sup> are two electro-magnets made by coiling the circuit wire a few times round short length soft iron rod about  $\frac{3}{16}$  in. in diameter. The electro-magnets lift up two steel balls taken from the crank bearing of a cycle. Small pieces of cigarette paper were interposed between

Fig. 2.

poles of the electro-magnets and the balls. On breaking the circuit with the key K, the ball B falls in front of an inch rule, FR, graduated in sixteenths of an inch, while simultaneously B<sup>1</sup> falls on the release lever K of the mouse-trap and snaps the shutter. The whole apparatus showed quite appreciable mechanical inertia, so that a measurable time elapsed between the impact of B<sup>1</sup> on K and the opening of the shutter. For high shutter speeds the height of E<sup>1</sup> at

K was increased in order that the ball B might be caught in the later portion of its 18 in. fall from rest, and so leave a conveniently long record of its progress on the photographic plate. If necessary for very low shutter speeds, the height of B above K could be lowered as far as was consistent with the sensitiveness to shock of the trap.

Fig. 2 is a reproduction of one of the photographs obtained. The shutter opened when the top of the ball had fallen 9.16 in.; it closed when the bottom of the ball had fallen through a height of 10.1-16 in. It will be noticed that the photographic trace of the ball falls off in density at each end, the decline being more rapid at its upper extremity.\* This cannot wholly be ascribed to the time required for actually opening and closing the shutter, for even with a shutter of ideal efficiency the photographic trace of a body of finite size must, from the very nature of the case, be more or less nebulous at its extremities. As can be seen by scaling Fig. 2, the breadth of the trace is  $\frac{1}{4}$  in.—i.e., the diameter of the ball was  $\frac{1}{4}$  in. When the shutter opened, the centre of the ball was therefore opposite 7 11-16 on the foot rule; when the shutter closed, the ball centre was opposite to the 9 15-16 division on the scale.

To evaluate the shutter speeds from such data as the foregoing I made use of the curve in Fig. 3, which plots the relation between distance fallen through from rest in sixteenths of an inch on the one hand, and the time taken in decimals of a second on the other hand. Drawing horizontal abscissæ from the axis of distance fallen at the points 7 11-16 and 9 15-16, and then vertical ordinates from the points where these abscissæ intersect the curve, it is seen that the time of exposure was .2268 — .2000 seconds = .0268 second = 1-37 second. These experiments furnished my initiation into the questionable ethics of the shutter-speed marker. The camera—a hand-camera of French make—had ostensibly a range of seven shutter-speeds, numbered empirically from 1 to 7, and in the trustful innocence of my novitiate I fondly believed this

\* Were I to repeat these experiments I should, with a view to a more pronounced and definitely definite photographic record, be inclined to substitute for the bright red balls formerly used two short iron cylinders painted dead black.

meant that the highest speed was seven-fold the lowest. My experiments, however, soon showed me that the highest speed was only about 1.3-7 times the lowest, and that in spite of all the specious mechanism for the variation of the shutter-speeds I had command of practically only two speeds—to wit, 1-37th and 1-50th of a second.

Fig. 3.

More recent experiences in shutter-speed testing by other, perhaps similar but not more accurate, methods, have led me to conclude that Mark Twain was not a photographic devotee when he threw current on our vernacular such a feeble and emasculated simile as "lying like a gas-meter."

DOUGLAS CARNEGIE.

## BRUSH DEVELOPMENT, OR LOCAL TREATMENT OF NEGATIVES WHILE DEVELOPING.

[The following note, by a Philadelphian professional photographer, is contributed to our contemporary of that town, the "Bulletin of Photography," where it is illustrated by a portrait which is certainly an excellent argument in favour of the method, presuming that the use of the developer has been largely responsible for the result.—Ems. "B.J."]

The following is the method I have found most successful for local work on negatives. The developer used is the old standby B. C. Pyro. [We interpolate the formula, which is evidently that for the Seed plates, though not included among the latest instructions in this country for the use of these plates.—Ems. B.J.]—

A. Water .....	8 oz.
Sulphite of soda (crystals) .....	$\frac{1}{2}$ oz.
Pyro .....	1 oz.
Citric acid .....	10 gr.
B. Water .....	16 oz.
Sulphite of soda (crystals) .....	4 oz.
C. Water .....	16 oz.
Carbonate of soda (crystals) .....	4 oz.
To develop take—	
A .....	$\frac{1}{2}$ oz.
B .....	1 oz.
C .....	1 oz.
Water .....	8 oz.

I make up two forms of solutions, one the regular one ounce

of each to eight or ten ounces of water, as you would in developing straight, the other, separate the carbonate from the pyro and sulphite by making up a solution in regular quantities of pyro and sulphite with the regular amount of water. Then use a solution of one-half carbonate and half water, or two-thirds carbonate and one-third water, whichever you find will suit for the strength of the negative desired. Now, we will suppose you have your negative exposed with a subject in white drapery. You develop the plate until your general composition is apparent on the surface of the plate, then pour off this regular developer and wash the plate. Now pour on the pyro and sulphite solution which you have previously made up, and hold the negative up to the light in the hand, FLAT, then use a brush, or soft cotton, saturated with the carbonate solution, and rub over that portion of the negative which you wish to bring out the most prominently. This must be done the first time very quickly, placing the negative immediately back in the solution, and then repeat the operation, blending the carbonate well over the plate so as not to get streaks. There is no special method of manipulation which will suit all cases. Each individual worker will

have to experiment in his or her own particular way for his or her own particular result. The principle involved is this: The negative is developed only to a slight extent in the first immersion, and as soon as the pyro and sulphite solution is poured on, development practically ceases. Then you control the accent of high-lights absolutely with your carbonate solution. Considerable practice will have to be had in most cases before you become master of this form of local work. I should caution the

beginner to under-time rather than over-time negatives for brush development, as the full-timed negative is much harder to control. In developing a 6 x 8 or 8 x 10 plate I use a one-inch camel's hair brush for the first brushing, going all over the plate with this, twice over the parts I wish to accent to one over the other part of plate. Then a brush less than half the size also of camel's hair can be used for pointing up.

RYLAND W. PHILLIPS.

## THE ACTION OF RESIN AND ALLIED BODIES ON A PHOTOGRAPHIC PLATE IN THE DARK.

(A paper read before the Royal Society and reprinted from the "Proceedings" of the Society.)

In former papers it has been shown that certain metals, woods, juices of plants, etc., have the property of acting on a photographic plate in the dark; that a similar action is exerted by coal resins and allied bodies is proved by the following experiments.

Ordinary resin or colophony is the solid remaining on the distillation of crude turpentine, and the substance known in commerce as "amber resin" is ordinary resin slightly purified, and is of a lighter colour.

To prove the activity of these bodies it is only necessary to lay them on a photographic plate in the dark, and afterwards to develop the plate in the ordinary way. The plates used in the following experiments were in almost all cases "Imperial Special Rapid." At ordinary temperatures the action is but slow; the contact of resin and plate would have to be for two to three days in order to obtain a fairly good picture. The amber resin is, however, slightly more active than the ordinary resin. If the temperature be raised, and contact be at 30 deg. to 40 deg. C., the action is much more rapid, and three to four hours is long enough to give a good picture. In fact, in four hours, ordinary resin will give as much action at 40 deg. as it would in three days at 15 deg. to 20 deg. A still higher temperature cannot be used with safety, for then the resin softens and adheres to the photographic film.

Absolute contact between resin and photographic plate is not necessary, for if the plate be held above the resin the action still takes place, and will, in fact, pass through a considerable distance. In one case when powdered resin was placed at the bottom of a glass cylinder and the dry-plate on the top at a distance of 120 mm., and in another case when the distance was 210 mm., in both cases after 18 hours' exposure at a temperature of 40 deg., a dark picture was produced. Another experiment which shows this action of resin was made by filling a glass tube, 1 inch in diameter and 10 inches long, and slightly contracted at one end with small pieces of resin, the tube being held in a horizontal position, and a dry-plate placed vertically at 1 mm. from the open end of the tube. On passing a slow current of air through the tube, which was maintained at 40 deg. C., a dark indication of where the air struck the plate was produced in two hours. On continuing to pass air through the tube the activity of the resin gradually decreases, but if the resin be taken out and again broken up its activity is restored.

If the tube containing the resin instead of being straight is bent at a right angle, and a dry-plate be placed below the bend, on passing a slow current of air through the tube a large amount of action is produced upon the plate.

The presence of oxygen appears to be necessary for the action to take place.

Two slabs of resin were placed separately in two desiccators: one was filled with dry air and the other with dry carbon dioxide; a photographic plate was fixed at 1 mm. below the resin plate, and both desiccators were kept at 40 deg. C. for 18 hours. It was then found that, although considerable action had taken place in the desiccator filled with air, none had occurred in the one filled with carbon dioxide.

A very marked and important character of this action of resin is that it is not able to pass through the thinnest sheet of glass or mica or aluminium. Glass 1/200 inch thick and mica 1/750 inch thick absolutely prevents the action passing through. This seems to separate this action from others of a somewhat similar character.

Another important point with regard to the action of resin and other allied bodies is the form of the shadow which they produce. If, for instance, a glass screen is placed in front of a piece of resin on a photographic plate the shadow is not bounded by straight lines, but the action, like that of a vapour, creeps in behind the screen, and in time meets from both sides. To prevent this action arising from any side action of the resin plate, a glass tube was filled with resin and directed against the centre of the screen. The experiment was repeated with the same apparatus, and a copper screen and ordinary light. Fig 1 (a and b) shows the effect produced in the two cases.

With regard to other properties of the resin plate, a thin plate acts as energetically as a thick one; thus a plate only 0.017 inch thick gave a picture of the same density as one 0.29-inch thick.

To obtain a suitable slab of resin for experiment it is best to melt

the resin and cast it on a bright metal plate, and afterwards, to free the surface which has been in contact with the metal from air bubbles, to pass a gas flame over it.

Another way of using resin for experiments is to dissolve it in alcohol and saturate a card or paper with the solution and allow it to dry. Even very dilute solutions may be used: a card which has been soaked in an alcoholic solution containing 0.25 per cent. of resin will give a dark picture, and with solutions of only 0.125 and even 0.086 per cent. of resin, faint pictures may be obtained. Again another way of using resin is to pour the alcoholic solution on to a glass plate and allow it to dry there. There are, of course, other solvents which may be used in place of alcohol.

A card prepared with an alcoholic solution of resin was placed in the dark slide of a camera, and the light of an arc lamp focussed upon it for five minutes. The card was then put up with a photographic plate at 55 deg. for one hour. A good and dark picture of the arc was obtained.

If resin be heated to a temperature of 40 deg. to 50 deg. for a short time it does not affect its activity, but if the heating be continued for 20 or 30 hours it slightly diminishes it. At higher temperatures the action is more marked; for instance, at 140 deg. the activity of the resin is much decreased after only four hours' heating, and, although resin may be fused without appreciably diminishing its activity, still, if it be kept in a liquid state for three or four hours, its activity is much decreased. An interesting experiment is easily made with a slab of resin owing to its brittleness. A weight placed on the slab cracks it in all directions; this can be slightly warmed on the underside so as to prevent its falling to pieces, and then on putting it up with a dry-plate for a short time

dark picture of the cracks is obtained (fig. 2). Another interesting experiment shows that the activity existing in resin can be transferred to a non-active body, making it as active as the original resin. A glass vessel was nearly filled with crushed resin, and a piece of inactive Bristol board placed on the top of it, at a distance of 5 mm. above the resin. This was left for a week at ordinary temperature, then on putting the Bristol board in contact with a dry-plate at 55 deg. C. for five hours a dark picture was obtained.

There are other ways in which this action of resin may be diminished or destroyed; for instance, by the action of sulphur

oxide. A slab of resin was broken into two pieces; one was placed for five minutes in a saturated solution of sulphur dioxide, then very thoroughly washed and dried; the other piece was treated in the same way, but with water alone, and both pieces were put up at 55 deg. C. for 18 hours. The one which had been washed with water alone gave a dark picture, and the one treated with the sulphur dioxide gave no picture.

### Excitement of Resin by Sunlight.

It has been shown in a former paper that wood, after exposure to sunlight, has its power of acting on a photographic plate in the dark much increased, and this increase of activity is not permanent, but gradually passes away. Resin acts in the same way: expose it to sunlight or to the arc light, and then bring it in contact or proximity to a plate, and it will be found that its activity has been greatly increased. Fig. 3 shows the picture given by the resin in its ordi-

nary state and after exposure to the arc light for half an hour. In one experiment a slab of resin was exposed to a bright July sun for 10 seconds, and this caused no increase of activity; but after 30 seconds, a slight increase occurred, and after an exposure of 60 seconds the activity of the slab had greatly increased; but on a still longer exposure no further increase took place, so that in about 60 seconds the resin was charged to its maximum amount. Another experiment, when the exposures were for 1 minute, 5 minutes, and 15 minutes, the 1 minute and the 15 minutes gave similar results. When the arc light was used in place of sunlight the same kind of action was observed, only more slowly. In one experiment the exposures were for 5 seconds, 15 seconds, and 30 seconds, and no marked increase of activity took place, but after 60 seconds' exposure a great increase was evident. With another sample of resin exposed to an arc light

it was found that it required 5 minutes' exposure to obtain its greatest amount of activity.

If amber resin, in place of ordinary resin, be used, it requires a longer exposure to light to charge it to its greatest amount. Resin is, however, a body which varies so much in composition and constitution that exact measurements cannot be relied on for different specimens, and the above experiments are only intended to show the nature of the action which occurs. The effect of heat on resin in its ordinary state has already been described; if, now, a resin slab, charged to its maximum by exposure to light, be heated to 55 deg. C. for only one and a half hours, all this extra activity is destroyed, and it returns to its original state of activity.

This increased activity induced by light acts generally in the same way as the original activity of the resin: it is destroyed by sulphur dioxide and does not pass through glass, mica, etc. In all cases of stimulating resin by the action of light a short interval occurs after the application of the light and before the increase of activity begins; when once begun, the increase takes place rapidly and it soon becomes charged to its maximum, so that longer exposure produces no further increase of its activity.

In order to ascertain which rays of the spectrum were most active in producing this change, a spectrum obtained from an arc lamp, with a quartz prism and lens, was allowed to fall upon a slab of resin for one and a half hours, and this gave, after contact with a dry-plate for two hours at 40 deg. C., evidence of action having taken place where the blue rays had fallen on the resin and not elsewhere. On placing slabs of resin in double bell jars with different coloured liquids, the blue, a solution of ammonia sulphate of copper, and the red, potassium bichromate, it was found that, even after an exposure of one hour in strong diffused light, the resin which had been exposed to the blue light had been strongly acted on, and gave a good dark picture, while the one exposed to the red light gave no increase of activity. The amber resin acted in the same way. A beam of blue light or of red light thrown on a slab of resin or a card saturated with resin gave the same results. On exposing resin under different coloured glasses the same effects were produced: after an exposure of one hour to bright daylight, under a blue glass, the resin became very active, under a red glass no change took place, and under a green glass there was only a very slight increase of activity.

It thus appears that the action of light in this respect, on resin, is similar to its action on wood, as described in a former paper. This increased activity of the resin slowly passes off, even at ordinary temperatures, on keeping in the dark or in red light. A slab was exposed to the arc light for one hour and then cut up into eight pieces. One piece was put up with a plate at once at 40 deg. C. for two hours; it gave a good dark picture; the other pieces were kept in the dark at ordinary temperatures: after three days a piece was tested, the picture it gave was only slightly lighter than the former one. After nine days, again, a loss of activity had occurred and the same was the case after 18 days. The experiment was carried on for nine months, and at the end of this time, although the picture it gave was much fainter than the first one, still it was slightly darker than the picture it would have given before exposure. If the resin be only slightly stimulated by exposure to bright daylight, the same gradual decrease of activity was traced. In red light the decrease was apparently the same as in darkness.

Although glass and some other bodies are opaque to the action of resin, porous bodies, of course, allow the action to pass through; for instance, with ordinary paper, if a slab of resin be placed behind it, a very good sharp picture is obtained; if, however, the paper be highly glazed and dressed, it is perfectly opaque. With ordinary papers interesting pictures, showing their structure and water-mark, and stencil pictures are easily obtained.

If paper be treated with different substances in solution, it is made more or less transparent. As a general rule it would seem that acid salts, such as the sulphates, which do not act on the photographic film, make a paper opaque, but that neutral salts do not alter its transparency. If a paper be dried by warming it, it becomes rather less transparent.

### The Effect of the Acid of Resin.

The principal constituent of resin is said to be an acid, known as abietic acid. It is not a body which has been thoroughly examined, but it has the property of acting on a photographic plate in the

dark to a remarkable extent. It can be obtained by dissolving resin in alcohol and passing hydrochloric acid gas into the solution; the acid then separates out in a crystalline form. By repeating this process it may be purified, and will then have a melting-point of 156 degrees C. It is with an acid so prepared that the following experiments have been made. If a small glass vessel be nearly filled with the crystalline acid and a dry-plate be laid on the top, not touching the acid, at ordinary temperatures, after two hours no action will have occurred, but after 18 hours the plate will give a strong dark picture. If, however, the acid be kept at a temperature of 40 deg., then a fairly good picture can be obtained in two hours, and with longer exposure a very dark one.

Thus it acts in the same way as resin, and has about the same amount of activity. Exposed to sunlight or to the arc light, its activity is much increased. Exposed to the arc light for an hour, it gives a good and dark picture, and even on an exposure of half that time a picture only slightly lighter is obtained; in fact, in little more than half an hour it is charged to its maximum amount. Light acts upon it as it does on resin.

The acid dissolves readily in alcohol, and if the solution be allowed to evaporate on a glass plate, it gives a film suitable for experimenting with. Paper saturated with the solution becomes very active. The acid also dissolves in ether, benzene, chloroform, etc., and behaves in the same way as with an alcoholic solution.

If the acid be heated to 100 deg. it slowly loses its activity; after eight hours' heating the picture it gives is only slightly fainter than before heating, but after 56 hours' heating it has become much fainter, and after being heated for 162 hours it has lost entirely its power of acting on a dry-plate.

If the acid be fused it becomes quite inactive, but its activity is restored if it be powdered, or if its surface be rubbed with sand-paper—in fact, if the smooth surface be broken up. If exposed to sunlight or to the arc light its activity is much increased, and different coloured rays affect it as they do resin. Exposed under blue or white glass to six hours' sunshine it gives a dark picture, but under a red glass only a faint one. All the metallic salts of this acid are entirely without action on a dry-plate; neutralise a solution of the acid with potash or soda and its activity has gone, and there is the same loss of activity with the copper and the lead salts, whether in solution or in the solid state. Decompose the metallic salts and the liberated acid is as active as before.

To purify the acid the lead salt, which is very insoluble even in alcohol and other organic liquids, was boiled several times with pure alcohol, and afterwards treated with sulphuretted hydrogen, the acid well washed and dried, and recrystallised from alcohol, and it was found to be quite as active as before this treatment. Another specimen of the acid was treated with an insufficient amount of alcohol to dissolve the whole of it. After boiling and digesting for a considerable length of time the undissolved acid was filtered off, washed and dried, and was found to be quite as active as before this treatment, so that neither process of purification affected the activity of the acid. If the fused and inactive acid be simply exposed to light it will again become active. If the activity of turpentine depends to any appreciable extent on the presence of abietic acid, then if it be treated with an alkaline body its activity should be decreased. Turpentine is known to be a very active body, and a plate placed about one-eighth of an inch above it will, even at ordinary temperatures, in three hours give a black picture. Some turpentine was allowed to stand for 18 hours with a small amount of solid caustic potash; this was then filtered off, and the liquid distilled and put up with a dry-plate for three hours; no trace of action was visible. Another dry-plate was placed above the same turpentine solution and allowed to remain for 18 hours; even then only a very faint action took place. Another specimen of turpentine was shaken up with magnesium oxide and allowed to stand for 24 hours. The clear liquid gave a much fainter picture after this treatment. The same occurred when dry sodium carbonate was used, but lead acetate had no action on the turpentine.

### The Action of Amber on Photo-Sensitive Surfaces.

Amber, although classed as a resin, differs so much from the substance already described that it was of much interest to ascertain how it would act under similar conditions. It is a remarkable

substance, known from the earliest times, and has been used for many purposes.

Quarried at one time, like a stone, it was naturally looked upon as a mineral, but is now known to be of vegetable origin: the extinction of certain trees, probably mostly coniferous ones, which have been buried in the ground for ages. Even in the Green-sand formation some amber has been found. At the present time the principal supply of amber comes from the shores of the Baltic, but a small amount is still picked up on the east coast of this country.

If a piece or pebble of amber, either in its rough state or cut as to give it a flat surface, be laid on a photographic plate in the dark, no action takes place, even if the contact be continued for hours and the temperature be at 40 deg. to 50 deg. C., thus differing from resin. This has been tried with a large number of specimens from different parts of the world, and with true amber has always been found to be the case.

There are many bodies closely resembling amber in appearance, chiefly resins, which act strongly on the plate, and although readily distinguished by an expert in the subject, can easily be mistaken for true amber. It often happens that a piece of amber, after long exposure to a plate, will develop on it small spots of action; the local actions are produced by fine cracks in the amber, which frequently occur, and it is above the opening of these cracks that the action takes place. If the amber be laid for a minute on a hot surface the opening of the cracks fills up and the action ceases. This resembles the action of resin, and apparently points to the collection of volatile matter within the cracks.

Another way of showing that, although a flat surface of amber does not act on a plate, still there is a trace of active vapour connected with it; for if powdered amber is placed in a glass dish with a plate above it, but not necessarily touching the powder, after the usual exposure a dark picture is produced. Amber, as is well known, is practically insoluble in alcohol, but in all cases a very small amount of some substance dissolves out of amber; now if the substance be collected by filtering the alcoholic solution and evaporating it to dryness, the residue is found always to be a very active body and gives a dark picture, thus a lingering indication of the amber's origin seems to be indicated.

Following the same line of experiments as that applied to resin, amber was exposed to sunlight and to the arc light, and its activity was found to be much increased. Four pieces of amber were exposed to sunlight for different lengths of time, namely, for two, three, five, and seven hours. After two hours only a very faint picture was produced; after three hours the picture was much darker and strongly outlined; after five hours it was still darker, and after seven hours a very dark picture was produced. The arc light acted in the same way. A specimen of good amber was cut into four pieces, and all of them were exposed at the same time, at a distance of 9 inches from the arc light: one piece for one hour, another for two hours, and the other two for respectively four and six hours. All of them were afterwards put up with dry-plates at 55 deg. C. for 18 hours. The amber exposed for one and for two hours did not act on the plate; the one exposed for four hours gave a considerable amount of action, and the one exposed for six hours gave a dark picture. Another experiment of the same kind showed that the amber became slightly active in two hours, and was much increased after four hours, but after six hours and even after ten hours but a very slight increase of activity occurred. As amber is a body which varies so much in constitution and composition, the action of light on it will vary slightly with every sample. For instance, five pieces of amber, all from different sources, were exposed at the same time for three hours to an arc light: two of them gave dark pictures, two only faint pictures, and one no picture at all.

Amber, like resin, if stimulated to increased activity by the action of light, gradually loses this increased activity on keeping it in the dark or in dull light, but for a long time retains a slight amount of its increased activity. If, however, the amber be heated, this loss of activity takes place rapidly, even when heated to only 50 deg. C. and if a flat surface of it be brought in contact with a piece of heated metal for one minute the amber loses entirely its activity. It has already been shown that resin is stimulated especially by the blue rays of the spectrum; the same thing occurs with amber. Specimens of different ambers were exposed both to sunlight and to a light under different coloured glasses, and it was always found that under the blue glass it became strongly active and that under the

ed glass it remained quite inactive, and if black glass and colour-glass were used the black glass acted like the red glass and the white one like the blue, only rather stronger. When double bell glasses with coloured liquids were used in place of coloured glasses, exactly similar results were obtained. One experiment of this kind was continued for four months and gave the same result.

Lignite, jet, and peat have also been tested in the same way as resin and amber. Two specimens of lignite from the Museum of Practical Geology, Jermyn Street: one an ordinary brown coloured piece, the other a sample from Tasmania; both were quite inactive and light did not stimulate them to action; even the alcoholic extract was inactive. Another specimen from Nigeria was also inactive, but one from Bovey Tracey was slightly active, and a specimen of "Brown coal" from Victoria, after an exposure of 44 hours, was found to be also very slightly active. Several specimens of jet from different sources were tried. None of them, if simply laid on a photographic plate and warmed, gave any action, but if powdered and a plate placed at 1 mm. above it, at 55 degrees for 18 hours, gave a faint picture. Again, if powdered jet was extracted with pure alcohol, the small amount of dissolved matter evaporated to dryness gave a dark picture. So that jet, although not in ordinary conditions an active body, still in the form of powder has the property of acting on a photographic plate. Light does not appear to have the power of making it active.

Graphite from Ceylon did not act on a photographic plate. A specimen of peat was found to have the property of acting on a photographic plate, but its activity was not increased by exposure to light.

#### The Action of Coal on a Photographic Plate.

One other substance belonging to this class of bodies—namely, coal—remained to be examined, and it was interesting to find that all ordinary coals, if brought into contact with a photographic plate at a temperature of about 50 degrees, were capable of acting upon it and giving a clear and distinct picture; so sharp are these pictures that they may be enlarged five or six times and still show clearly all the details. Through the kindness of Dr. Teall and Mr. Strahan, of the Museum of Practical Geology, I have had the opportunity of examining coals from different localities. Taking first the specimens of English coals, they all seem to be active, that is, have the power of acting on the photographic film in the dark. The best way of trying them is, first, to saw off a piece from the rough block, and then rub it down first on coarse sand-paper and then on fine, till the surface is flat and true, then on laying this flat surface on a photographic plate at about 50 deg. C. for in most cases about 18 hours, but in some cases it may be well to continue the contact for as long as 48 hours, a good picture is obtained. If the coal contains much water it must be dried, either by heating it for a short time at a temperature of about 40 deg. C., or by drying it over sulphuric acid.

In place of using a slab of coal, it is sometimes convenient to use it in the form of powder, and this is done, as in previous cases, either by simply placing the powder on the photographic plate or by filling a small glass vessel with it and placing the photographic plate at the top, either in contact with the powder or at a small distance above it. As long as the coal is used in form of a slab and is fairly dry, its action is very uniform, different pieces of the same coal giving pictures of the same density; but when the coal is in powder, a small amount of moisture modifies the density of the picture to a very considerable extent.

The effect of slightly heating a coal is shown by the following experiment:—Four samples of a Seaham coal in powder were treated as follows: One sample was at once put up with a plate, and gave a fairly good picture; another was heated for 24 hours at 100 deg. C., and gave a much darker picture; a third one was heated at 50 deg. for the same length of time, and its picture was much lighter, only slightly darker than the first one; and the fourth sample was heated for 24 hours at 200 deg., and gave no picture.

In another case the heating was continued for only three hours at 200 deg. and it gave a faint picture. If the drying be effected by placing the powder over sulphuric acid, phosphorus pentoxide, or solid caustic potash, it seems in many cases to increase the activity of the coal to a very considerable extent, so much so that some coals which under ordinary conditions give only a faint picture can be made to give a dark one. But on the other hand

there are coals which are not altered by this process of drying. In the specimen of coal, a Seaham coal, powdered was exposed 11 times to a glass vessel over sulphuric acid, each time for 24 hours, with no diminution of its activity; but if the coal was exposed to the air for 24 hours its activity considerably decreased, but was restored by again placing it over sulphuric acid.

Coals exposed to sunlight or arc light do not perceptibly increase in activity, as many other bodies do, nor does the small amount of substance dissolved out of them by boiling alcohol appear to be active.

#### Differences Between Coals.

Although there must necessarily be a strong resemblance between coal pictures, still it may prove that a certain specific and recognisable character belongs to coals from different beds. For instance, judging from the few specimens which have been examined, the South Wales coals appear to have their active strata fine and near together, whereas the coal from Derby and Nottingham has active strata which are much thicker and very sharply defined; but considering the small number of experiments made, this may be purely accidental. The pictures, however, clearly show differences in coals; for instance, all the anthracites that have been examined have given pictures different from the foregoing: they are fainter in appearance, the structure they represent is more complicated and the active matter more evenly distributed through the mass of the coal. There always appear to be cracks in anthracites, and these cracks are always white. There is also another curious point with anthracites: if they are dried over sulphuric acid the picture they give is much darker than the picture obtained in the ordinary way. Only a few Cannel coals have been examined: these gave pictures in character like the anthracites, but with less detail and not so dark.

From coal plants of different kinds and from different localities no pictures have been obtained. If the soft powder so common in bituminous coals and known as "Mother of Coal" is carefully removed and tested it is always found to be very active. The fibrous substance so often present and easily removed from coal is also very active, but the hard glistening surface of coal is only slightly active. Of the coals which have been examined, a Boora coal from the Lower Oolite, a Jurassic coal from Mexico, and some Argentine coals and a Tertiary coal from India are ones which have been found to have little or no action on the photographic plate. No doubt the long exposure of small specimens in a museum may affect their activity.

The foregoing experiments indicate the nature and to some extent the results which may be obtained by allowing coal to draw its own picture on a photographic plate, and in the hands of a geologist may help to explain the process of its formation.

#### A Theory of the above Actions.

With regard to the nature of this action on photographic plates in the dark, it has been suggested in former papers that it is owing to the presence of hydrogen peroxide, and that the effects described can be imitated by means of this body. It now seems that actions of this same kind are obtainable from many other bodies, but still bodies of the same kind, and these additional experiments strongly indicate that the action is produced by a vapour rather than by any form of radio-activity. For instance, it is shown that the shadows thrown by resin are not bounded by straight lines, but curve round a screen; that the action is not capable of passing through glass, mica, or aluminium foil, even of extreme thinness, and does not affect an electrical field. The action can pass along a glass tube, even when it is bent at a right angle, and may be swept out of a tube by a slow current of gas; and, further, an experiment described above shows that the activity of resin can be transferred to a piece of perfectly inactive Bristol board, which will then give a black picture. Further, no action takes place in an atmosphere of carbon dioxide. On the other hand, resin dissolved in an inactive liquid, such as alcohol or petroleum spirit, causes it to become active.

The action which strong light has in increasing the activity of many bodies is important. For instance, it has been shown that pith may be in contact with a photographic plate at 55 deg. for 48 hours and no trace of action is visible, but if the pith be exposed

darklight for two or three hours it will then give a dark picture. In some action occurs with old printing, with pure india-rubber, and many bodies which under ordinary conditions are but slightly active become very active after exposure to bright light or simply to blue rays.

My thanks are due to my assistant, Mr. Bloch, who has made all the photographs and given me much aid in carrying out the experiments.

The work has been carried on in the Davy-Faraday Laboratory of the Royal Institution. W. J. RUSSELL, PH.D., F.R.S.

## POSING FOR ENGRAVINGS.

[One of the profit-earning branches of photography which we find photographs for advertisement. The importance of a really good rarely a demur on the part of the purchaser to pay a good price, and the advertising manager of a large photo-engraving firm may be directly helpful in this class of work, but because they call attention Eds. "B.J."]

THE chief aim of illustrations showing articles of merchandise offered for sale is to arouse in the mind of the observer a desire to purchase. To attain this end advertisers frequently resort to the plan of showing the article in use. This not only gives an idea of the manner of manipulation, but care is usually taken to show the article in a way that will convey a favourable impression regarding its adaptability to the purpose intended and ease with which it may be manipulated. This plan of illustration is usually most effective with articles that are in themselves unattractive and rather difficult to illustrate in an interesting manner.

Undoubtedly the most attractive illustrations are those reproduced by the half-tone process. This gives photographic effect, and is usually more realistic than illustrations made from pen drawings. There are two methods of producing illustrations for half-tone reproduction. One is by taking a wash drawing of the figures to be shown; the other is by making photographs of models posed for the purpose. As a rule, when drawings are used, only those of superior artistic merit are desirable. Drawings that are incorrect in proportion or lacking in the essentials of correctness are undesirable, and are usually detrimental to the advertisement in which they are used. This means that drawings must be of good grade, and therefore somewhat expensive.

The growth of amateur photography has been an important factor in promoting the popularity of photographs of models in connection with advertised articles. A large percentage of the population is more or less familiar with photographic processes, and therefore more or less curious regarding illustrations which are manifestly made from photographs. It is sometimes rather difficult to determine whether an illustration is made from a wash drawing or a photograph, but, as a rule, the distinction is easily made and interest in the illustration correspondingly increased.

The demand for models in connection with advertisement illustrations makes it necessary for concerns engaged in this line of production to have a large list of available models, subject to call at all times. These models comprise people in all walks of life. It is not

being followed *sub rosa* by many a professional is that of preparing photograph to an advertiser makes this work one for which there is therefore the following notes (from the "American Printer") by be recommended for study, not because they contain much that is to the many profitable applications of clever work of this kind.—

at all unusual for young women occupying social positions of prominence to offer their services as models for photographic purposes. These women are always possessors of good figures and usually have faces which produce pleasing photographs. They are very desirable as models, for the reason that their carriage is usually graceful, and they are more intelligent than the average professional model. As a rule, they object to having their faces reproduced without alteration, and this is accomplished by retouching the photograph in such a way as to make it unrecognisable without this change being apparent to the observer.

Actresses sometimes offer their services as models, and, as a rule, they are the most satisfactory of any class available for this purpose. Their training enables them to grasp the spirit of the occasion, and the result is usually a picture possessing a large amount of human interest. The producer of commercial photographs must rise to the spirit of the occasion to produce the best results. Usually the article to be shown suggests ideas that are not particularly difficult of execution. The advertiser frequently has ideas that are more or less definite, but occasions frequently arise where the advertiser is completely at sea and unable to suggest a method of showing the article which he fully realises is of the most prosaic nature. The article itself is about as interesting as a sand pile. Under the magic hand of the expert, however, a series of illustrations is prepared by photography showing an entire process of making from start to finish.

The cost of photographs produced from models is an uncertain quantity. A model is usually paid by the hour, and, as a rule, several photographs are made in order to have a choice in selection. Sometimes very little retouching is required, and in other cases the retouching expense is considerable. As a rule, the cost is less than it would be if wash drawings of good grade were used. The wise advertiser, however, is after results, and the cost of engraving is not regarded as a vital point. He realises that when he expects to spend several thousand dollars for space in magazines, it does not matter if his engraving cost varies a few dollars. He knows that the money is well spent. F. B. MILLER.

## HIGH-SPEED PHOTOGRAPHY.

[Presidential address delivered by Mr. J. F. Duthie at the First General Meeting of the Edinburgh Photographic Society, for Session 1908-9.]

IN selecting a camera for high-speed work, the first essential is a shutter which will give very short exposures. There are practically only two forms of shutter now fitted to hand cameras, which for simplicity I might term as the lens shutter and the focal-plane shutter. The former is usually fitted between the combinations of the lens, and while it has the advantage of being compact and light, the lens is fully open for a fraction only of the whole exposure, so that this form of shutter does not allow the maximum of light to reach the plate. With the focal-plane shutter, on the other hand, the lens is fully open during the whole exposure, and as the slit of the shutter passes across the plate, the part of the plate exposed receives the full amount of light passing through the lens. It is impossible to draw a close comparison between the two shutters, or to say exactly how much better the exposure will be with a focal-plane shutter than with a lens

shutter, but an exposure of 1-200 part of a second with a focal-plane shutter would pass about the same amount of light as an exposure of 1-50 part of a second with a lens shutter, and the faster the shutter is used the greater will be the difference in favour of the focal-plane shutter. Thus the focal-plane shutter has a great advantage over the lens shutter for all classes of work, particularly when the exposures are of very short duration. The next consideration is the lens, and this is of extreme importance. It must be capable of giving good definition much beyond the extreme corners of the plate, so that the rising front may be used with the full aperture of the lens. It must also be of large aperture to allow of very short exposures. These requirements can only be fulfilled by the modern anastigmats, which are made with apertures varying from  $f/4$  to  $f/6.8$ , the former being preferable. It must be remembered, however, that depth of definition

depends on the aperture and focal length of the lens, so some compromise has usually to be made between the two. While a short focus lens giving good depth of definition is to be desired, because the blurring of distance by focussing has not to be so exact, it is objectionable because of its exaggeration of perspective. The longer focus lenses, although requiring more care in focussing, and if carelessly used giving a larger proportion of fussy negatives, gives better perspective, shows the operator to be farther away from the object, and gives an image of a fair size on the plate. In much high-speed work it is far more desirable to be near the object. But the choice of the lens must depend to a certain extent on the kind of camera to be used, whether the folding or collapsible type with direct vision finder, or the bulky but more efficient reflex camera. Of the two, I prefer the latter. The camera, lens, and shutter having now been considered, the next matter that calls for attention is the exposure. As a rule, for very high-speed photography a meter is useless. It is usually a case of the largest aperture of the lens, and the longest exposure the velocity of the subject will allow of. One exception to this, however, is shooting subjects, and here, owing to the much better light to be got at sea, a meter will often be found useful in deciding the best stop to use. The speed of shutter must be set according to the circumstances under which you are working, and they vary very much. In photographing from a pier or anything stationary, the points to be considered are the movements of the yacht, the distance she is off, and the length of focus of the lens. With a 5in. lens on a quarter-plate, or a 6 $\frac{1}{2}$ in. lens on a 5 by 4, an exposure of 1-100 to 1-150 part of a second will be ample, but, with the single combination of the lens, 1-200 of 1-250 will be required. In photographing from a small boat on a moving steamer, the speed of the shutter will require to be increased considerably. When arrangements have been previously made to photograph a yacht, or when photographing groups of yachts, it will be an easy matter to get them sufficiently large on the plate with an ordinary lens, but when trying to get pictures of single yachts from a steamer at a regatta, it will be found a great advantage to be able to use the single combination of the lens. On shore the light will not usually allow of the use of the single combination. At sports the exposure will vary principally with the angle and speed at which the subject is moving and the length of focus of the lens. Supposing the distance from the subject to be constant, the shorter the focus of the lens the slower the shutter can be used. Personally, I use an 8in. lens with an aperture of  $f/6$  to a 5 by 4 plate, and will give a few examples of the exposures I find necessary.

Runners coming towards the camera, 1-300; runners at a slight angle, 1-600; runners at right angles, 1-800. Jumpers much the same as above, but occasionally a slightly fuller exposure can be given if you study the style of the jumper.

For horses jumping and trotting at a slight angle, 1-800 second. For horses galloping at right angles, 1-1,200.

These may be taken as a general guide, but I will speak of others when showing the slides on the screen.

As to the plate to use. For sea work I prefer orthochromatic plates; in fact, I may say that they are essential. The intensity of illumination, the preponderance of the blue rays, and the delicate tone values require a colour sensitive plate, and, when the light will allow of it, a screen will be found a great advantage. A few years ago the one drawback to ortho plates was that they were rather slow, but great strides have been made lately in their manufacture, and a plate such as the Imperial "Special Sensitive" will allow very short exposures.

As a rule, on land, the fastest plate obtainable should be chosen, and it takes a very good plate to meet the requirements for subjects such as I have mentioned this evening.

It must, while having a fair amount of latitude, stand forcing in development, such as a very strong soda solution at a rather high temperature, without frilling or fogging. After having used several makes of plates, I may say I find the Ilford "Monarch" very satisfactory. It is astonishing what it will stand in the way of temperature and forced development, and the grain is very fine for such a rapid plate. I always prefer to use backed plates, and for yacht photography they are absolutely necessary. At sports, where the plates are usually clad in white, and especially where they have to be photographed with only the sky behind them, backed plates are of course a benefit. I have seen it stated somewhere that backed plates are slower than unbacked plates, and the theory put forward was that

the backing absorbs the light which penetrates the emulsion, while in the plate without the backing the light is reflected again on to the film. However, in practice I have not found, even after careful trials, any disadvantage by using backing.

In treating of development, I would first like to say a few words on the conditions under which it is carried out. Although very sensitive plates are used, the "dark-room," as it is called, should not be altogether a place of darkness. There should be enough light to see about. If you can readily see what you are doing, you can handle your plates smartly, and run less risk of fogging than when moving slowly about close up to a small light. It is surprising the amount of light fast plates will stand if it comes through good ruby glass or fabric. The time you have to be most careful with a fast plate is during the first minute or two of development, when it can either be kept covered or at a safe distance from the light. When the image shows up it may then be exposed quite safely to a good ruby light, and after it is fully developed and well rinsed, it can be even exposed to daylight without any harm resulting, although, as there is no benefit by this, it is really better, if convenient, to fix before leaving the dark-room.

With chromatic plates, and others which have been fairly well exposed, I prefer a pyro-soda developer. The Ilford or Imperial formulae I have found very satisfactory, but prefer to leave out the bromide of potass, unless I know the plates have been fully exposed. If the developer is kept made up without bromide, a few drops from a 10 per cent. solution can be added as required. In using these formulae I usually begin with the following proportions of 4oz. No. 1 to 1oz. No. 2, and about 1 $\frac{1}{2}$ oz. water. If, as development proceeds, the detail comes up readily, more of the pyro solution may be added to give density, and a little bromide to give the necessary contrast. With short exposures the best result will usually be got with the quantities mentioned. For "Monarch" plates where the exposure has been rather meagre, I take a pyro-metol developer, using a large proportion of the soda solution and a little warm water. A cold developer is not only very slow, but fails to give the requisite vigour to a negative. The best temperature to use the developer at is about 65 deg., but where the plate has been very much under-exposed it will be found an improvement to use it even warmer than this.

I would like to say a few words about photographing some of the most popular subjects which require a focal-plane shutter. From some photographs of runners at sports I have noticed some workers prefer to take them from right in front. In a short race, where the competitors are well together, this is the best way of getting them all in focus, but to my mind it gives the figures a most unnatural appearance. I much prefer to take them from one side and a little ahead, as it gives a much better idea of action in the figure. The same applies to high jumping and hurdle racing. With the latter it is better to choose a hurdle near the start of the race so as to have the competitors pretty well together, getting them all in focus, and thus conveying a good idea of keen competition. When photographing a golfer, I think the best position is just before the finish of the swing. The club has a good bend on it, and there is usually an alert look on the face of the player. Another good position is when the golfer is playing out of a bunker, the sand that is knocked up often helping the effect.

To get good results of horses requires some study of the animals themselves, as the results to be appreciated must show good action. Do not attempt to take them coming towards you with a short focus lens. In photographing yachts, also, it is better to have some knowledge of the handling of them if you wish the results to look well. Taken from a bad position, with bad lighting, or with the sails not "drawing" well, it is an easy matter to make one of the finest boats look a mere "hulk." In fact, to get the best work when photographing most of the subjects I have spoken of this evening, it is necessary to know your subject thoroughly first. The focal-plane worker more than any other must be alert, quick, and decisive, as usually the slightest hesitation means failure. When the time comes for making the exposure, don't clutch the camera vigorously and make a sudden jerk at the shutter release, as it will simply mean vibration of the camera and a spoiled plate. Don't get excited. Hold the camera easily, and with a gentle pressure of the finger release the shutter.

In conclusion, I expect it to be said that what I have spoken of is really summer work only, but I would just like to point out that the

principal apparatus required, viz., a focal-plane shutter and large aperture lens, is also the best material for getting successful pictures in winter.

J. F. DUTHIE.

#### AUSTRALIAN KODAK, LTD.

THE "Australasian Photographic Review," the organ of the Baker and Rouse Proprietary, Ltd., in its September issue just to hand makes the following statement:—

"We have to announce that the manufacturing portion of our business has been acquired, and will in future be conducted, by a company to be known as 'Australian Kodak, Ltd.'"

"The policy of this company will be directed by Mr. T. Baker and Mr. J. J. Rouse, and its objective will be to supply photographic goods equal to any in the world, and at prices, in most instances, not higher than those charged in Great Britain.

"To attain this object Mr. Baker recently visited the United States, and succeeded in arranging for the Australian manufacture of all the products of the Kodak factories which it is practicable to handle here, and the new company is now erecting large factories in Victoria for the establishment of an important industry, which will provide employment for a considerable number of workers, and at the same time place within reach of consumers the perfectly fresh goods which are so eminently necessary for all photographic processes.

"The requisite arrangements are being pushed forward with all possible despatch, and we trust soon to be in a position to announce a very considerable reduction in the prices of Kodaks, roll films, Velox paper, and most other Kodak productions.

"We therefore anticipate, and confidently ask from Australian photographers, both amateur and professional, such measure of support as an Australian industry is justified in expecting from Australians.

"All branches of our business throughout the Commonwealth will continue to be conducted under the name of Baker and Rouse Proprietary, Ltd., as hitherto."

## Exhibitions.

#### WESTERN COUNTIES.

THOUGH there is no great gain in numbers in the matter of prints, and not so much progress as those interested in pictorial photography in the West could desire, yet the collection of work is decidedly helpful to the ever-growing army of photographers. When the admittedly strong pictorial quality of the West is taken into account, it is curious that there are no more photographic societies than there are in Devon and Cornwall, which, for its area, is poor in this respect. This exhibition ought to quicken work into life, because it is not so ephemeral as most things of the kind, and a great number of people, to the total of many thousands, see the works that have been submitted. Of course there is an aim to encourage Western workers and the delineation of Western scenes, but there is little wrong with this—the West is clannish, and it has much to offer all who come that way, especially for photographic purposes. Of the exhibition as a whole it may be said that the average is moderate. There is no striking bit of work, nor anything very bad. There are examples of the shiny—probably there always will be. But, as a rule, the work is decently printed, and, usually, mounted quietly and in better taste than formerly. Even in the West this ought to be. It would be better for the workers in the West if they could see more examples from the best people, but the exhibition does not draw them so much as could be desired, and the country folk are not helped as they might be. Among works which rejoice in the inappropriate title of "champion" there is a fine thing, impressive and suggesting vastness and power—"Mauretania Leaving the Tyne," by Gladstone Adams, which just misses being a great thing. The fault is hardly the photographer's, but the accident of circumstance. E. O. Hoppé's "Student" is an impressive study of figure work. Dan Dunlop's "Edinburgh Castle from Grey Friars" is suffused with delicacy and charm, and the point of selection is happily chosen. J. C. Trudgeon's "Land's End," while a fine study of rocks and cliffs, suffers from having no sky whatever. A. B.

Fellowes Prynné's "Sand Dunes" deserve commendation. A. Stafford's "The Stag Rock" is quite a painter's subject, and handled very well indeed—especially in atmospheric quality. F. W. Beken's "Silver Sea" does convey the idea of the title: it is little flat and grey, still it is very enjoyable. E. T. Penrose's "Autumn in the Woods" does really convey the sentiment which the title suggests; and the same may be said of Graystone Bird's "To the Hills," which is probably as good as anything he has done in the line. Rev. W. E. Windle may be congratulated upon his selection of the charming subject—"Les Arcades, Bellagio," but not on the pronounced diffusion he has treated it to. So small a print will not stand so much "softening." Rev. E. T. Clark has certainly got a very charming thing in the "Triforium." J. S. German's "A Ray of Light" is a beautiful architectural interior; but "ray" is hardly the word to use. Miss Muriel I. Hunt's studies of "Cats" are really deserving of much more attention than they will get. The others are very well done. Thomas Hood's picture of a "Thrush at Young" is very fine work. A. W. Walburn's celebrated "A Sylva Scene" wins no more than deserved attraction and praise. Rev. H. W. Allen's "Grindelwald" is most impressive and technically first class. A beautiful little picture is Rev. S. Williams' "Finshauts," an Alpine scene. His "Ancient Mariner of Borgherla" is good, too. A. B. Fellowes Prynné's "A Sunny Day" is really suggestive of sunlight, and might have won higher distinction by a little change in composition. The work contributed by those who have never secured an award, and the juniors, is distinctly full of promise and is most encouraging. The judges were Mr. Walter D. Finch and Mr. F. J. Mortimer, who made a large number of awards.

#### THE WORK OF MR. WILLIAM CROOKE.

THE Edinburgh Photographic Society has arranged two one-man shows for this season by Wm. Crooke, Edinburgh, and J. Craigh Annan, Glasgow; the first of these is now open in the Society Rooms, Castle Street. Mr. Crooke's fame as a portraitist is well assured, and in this one-man show—surely the severest test that any artistic worker can be subjected to—he sustains, if he does not intensify, previous opinions. His work is that variety characterised as "straight," and the effects he obtains seem one of the strongest possible arguments for what is now scoffingly termed "pure" photography. If the personality behind the camera can, by the aid of his camera plus his own artistic instincts, obtain Crooke pictures, where is the necessity for the "personal control" so much boasted of by moderns? May not the personal control, as well, if not better, applied in the taking of the picture as in the faking of the print?

The exhibition shows Mr. Crooke's work in its many phases: the dignity of old age, the manliness of vigorous manhood, the grace of the débutante, or the bewitchery of the child; in all the "age" the characteristic of the time is apparent, and over and throughout all the hall-mark of Crooke is evident. That professional work can be highly artistic and at the same time "like" the sitter is evident here, and the E. P. S. is to be congratulated on placing such an exhibition before its members and the public. Earlier work was printed in carbon, but platinotype being much used in the work-a-day business Mr. Crooke found it more convenient to print in that medium, hence its adoption. The exhibition is quite up-to-date, and includes seven pictures the produce of this year's work.

Here we have a photographer who, business apart, follows photography not in its business aspect, but as an artistic pursuit, and therein you have the true amateur.

#### THE WORK OF J. M. WHITEHEAD.

It is fashionable in certain circles to despise, blatantly, the work of the country professional, and columns of elaborate satire have been hurled at the devoted head of the pro. with a sma' way o' dae. A one-man show, held in the rooms of the Glasgow Southern Photographic Association, promoted by the Glasgow Photographic Circle, however, gives the lie direct to the accusation of universal incapacity. The author of the fifty-three pictures on exhibition J. M. Whitehead, The Studio, Alva, known to the folks of the Borders as "the photographer," and known to a world-wide circle of admirers as a photographer of much merit. At the R.P.S. and

London Salon his work is always in evidence, while he shows his pride o' country by enthusiastically supporting the Scottish Salon. It was in still-life subjects that Mr. Whitehead first earned the acclamations of the exhibition-going public, and so new, so simple, and yet so satisfying was the work that came from his camera that he has been acknowledged to be among the leaders of the pictorial movement.

From his still-life pictures he wandered to landscape, and here he has evolved, or rather interpreted, a phase of landscape that has been identified with his name, and at any of the exhibitions a "Whitehead" is easily distinguished by even the most casual exhibition attendant. He does not practise any of the slap-dash methods adopted by many of the modern school, his pictures nowadays being all printed in platinotype, not by any means a process readily adaptable to the cult of "fake." Most of his work owes much of its power to composite printing, three or four negatives being occasionally used, but this is not visible to the finished product.

## Patent News.

*Process patents—applications and specifications—are treated in Photo Mechanical Notes.*

The following applications for Patents have been received between October 26 and October 31:—

**DEVELOPING.**—No. 22,670. Improved method and means for developing photographic films. John Gordon Hume, 122, George Street, Edinburgh.

**CINEMATOPHOTOGRAPHS.**—No. 22,970. Improvements in and relating to cinematography or moving pictures in colours. William Norman Lascelles Davidson, Rammore, Cross Road, Southwick, Sussex.

**GELATINE PAPERS.**—No. 23,020. Improvements in the manufacturing of gelatine photographic papers containing silver salts. Edwin Ebenezer Burnett, 2, Heber Road, Cricklewood, London.

**TRANSFER FILMS.**—No. 23,146. New or improved process for the manufacture of photographic transfer films. William Mounsteven Gillard, Chancery Lane Station Chambers, London.

**DAYLIGHT DEVELOPMENT.**—No. 23,148. Daylight developer. Alfred Hamburger and Heinrich Imhof, 33, Cannon Street, London.

**CINEMATOPHOTOGRAPH-PHONOGRAPH.**—No. 23,153. Improved means for securing synchronous movement in moving pictures and talking machines. William George Barker and William Cecil Jeapes, 55, Chancery Lane, London.

**COLOUR PHOTOGRAPHY.**—No. 23,273. Improvements in "carbon" processes for use in colour photography. Edgar Clifton and Arthur Ernest Wells, 3, Broad Street Buildings, Liverpool Street, London.

**CINEMATOPHOTOGRAPHS.**—No. 23,274. Means for angularly adjusting the feed-drums of cinematographs with Maltese cross-feed mechanism. Alfred Duskes and Duskes Kinematographen und Film-Fabriken G.m.b.H., 31, Bedford Street, Strand, London.

**CINEMATOPHOTOGRAPHS.**—No. 23,275. Means for securing automatic adjustment of the shutters of cinematographs coincident with the adjustment of the picture strip relative to the shuttered aperture. Alfred Duskes and Duskes Kinematographen und Film-Fabriken G.m.b.H., 31, Bedford Street, Strand, London.

**CINEMATOPHOTOGRAPH-PHONOGRAPH.**—No. 23,276. Improved method of and means for controlling the conjoint action of cinematographic and sound-recording apparatus for the purpose of securing synchronism. Alfred Duskes and Duskes Kinematographen und Film-Fabriken G.m.b.H., 31, Bedford Street, Strand, London.

### COMPLETE SPECIFICATIONS ACCEPTED.

Specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

**CERAMIC COLOUR-SCREEN PLATES.**—No. 22,228. 1907. The screen-plate is made by first of all coating glass with a suitable "tacky" substance, and then with ceramic colours or chemically stained "fluxes" in the proper proportions of the necessary colours for the negative or positive plates. After levelling with a squeegee or by application to pressure, these coloured sub-coatings are then

varnished if required, and afterwards super-coated with pan-chromatic or other colour-sensitive emulsion, or the plates may be covered evenly over with these ceramic colours or fluxes and then passed through a ceramic kiln or furnace. By the firing process they are melted, and form a coloured transparent glaze of the most minute particles of the necessary colours, which are chosen to form their required tints after firing. The process of firing fills up any minute spaces there may be between the coloured particles, and forms the coloured glass screen upon which the colour-sensitive emulsion is coated direct.

The colours used are composed of silica, minium, and borax, or with saltpetre added if required, and for the colours are oxide of cobalt for the blues, cupric oxide of copper or oxide of chromium for the greens, and with the addition of ferric oxide to either of the former for the reds, ferric oxide of iron or chromate of lead for yellow and orange, and gold with oxide of tin for magenta or pink, in their required quantities so as to obtain the necessary optically correct intense colours to reproduce the natural tints of the picture taken.

By this ceramic process all varnishes, mediums, and sub-strata are entirely done away with, and the sensitive emulsion can be coated upon the screen glass direct, and there will be no dissolving of dyes and no change of the original colours, and no frilling during development. The plates can be made in graduated shades of colour and blended to suit landscape, seascape, portrait, or highly coloured work, by depositing more or less of the powdered colour in different parts of the plate.

The inventor mentions that it has been previously proposed to form multi-coloured screens by means of coloured particles of glass melted into the supporting plate of the sensitive film. Henry William Hamblin Palmer, 45, St. Martin's Lane, Charing Cross, London, W.C.

**COLOUR SCREEN PLATES.**—No. 17,065. 1908. The invention relates to a method of producing colour screen-plates, which is based on the property possessed by various dyestuffs of behaving selectively towards other substances to be stained therewith. Thus, for instance, a dry collodion film is immediately stained blue on being dipped in an aqueous solution of basic methylene blue containing a little alcohol, whereas it stains with difficulty on being dipped even in a purely alcoholic solution of acid erythrosine. On the other hand, a dry gelatine film, which is difficult to stain, by immersion in a purely aqueous solution of methylene blue, acquires a stain at once when dipped in an alcoholic solution of erythrosine containing only a little water. If the two dyestuff solutions be mixed, and a film of gelatine and one of collodion be dipped simultaneously in the mixture, the dyestuffs separate, the collodion taking a pure blue stain whilst the gelatine is stained pure red. If a solution of gelatine that has been stained with methylene blue and treated with a little alcohol for the purpose of softening the collodion, be applied to a dry collodion film, the methylene blue migrates from the gelatine into the collodion. Conversely erythrosine will migrate almost completely from a collodion solution stained therewith, into a gelatine substratum.

This differential behaviour of the acid and basic dyestuffs toward certain substances, such as gelatine, collodion, laces, gums, resins, caoutchouc, and many others, are utilised for the production of three-colour screens as follows:—The substratum intended to receive the screen, and consisting of a film of gelatine, collodion, etc., is brought into contact with the dyestuffs, which are mixed with substances for which these dyestuffs have a less powerful affinity than they have for the film of collodion or gelatine. The dyestuffs then migrate from their carriers into the gelatine or collodion film, and after the dyestuff carriers have been removed, as, for instance, by washing, the three-colour screen is left in a finished state.

The manufacture of the screens is carried out as follows:—Three solutions of gelatine are prepared, and each of them is stained with a dyestuff possessing a stronger affinity for collodion than it has for the vehicle—e.g., gelatine. The stained solutions are then evaporated to dryness and ground to fine powder.

The three powders are mixed and applied to a freshly prepared and therefore still rather sticky collodionised substratum, either by sifting them through sieves on to the substratum travelling underneath, or else by means of a dusting-on device. The dyestuffs migrate from the powder into the collodionised surface, and

the powder, now colourless, is then removed by washing. Although in this method the coloured powders overlie each other to a large extent, no interchange of their dyestuffs occurs; but, on the other hand, uncoloured patches may remain in many parts of the substratum, owing to no colour having been absorbed, through defective contact between the powder and the substratum. This defect, however, may be remedied, as, for example, by dusting on only two differently coloured powders, and producing the third colour by treating the substratum in a bath containing the third dyestuff dissolved in a substance of such kind (*e.g.*, gelatine) that the dyestuff will migrate from it into the collodion, the gelatine being then removed by washing. Or, again, three differently coloured powders may be dusted on, a smaller quantity being taken of one than of the others, and the treatment then completed as above.

Instead of gelatine, a solution of gum arabic, for example, may be used for absorbing the dyestuffs, since for this substance also the dyestuffs have a lower affinity than they have for collodion. If, on the other hand, the substratum be coated with a film of gelatine instead of being collodionised, the reverse method is adopted, that is to say, the dyestuffs are dissolved in collodion, dried and dusted on to the substratum. In this case, of course, the dyestuffs dissolved in the collodion must be such as exhibit a greater affinity for collodion, and will therefore migrate from the coloured collodion powder into the gelatine film.

Instead of dusting the substratum over with coloured powders, it may be sprayed directly with the coloured liquids, for instance, with the above-named three-coloured gelatine solutions or the like, simultaneously or in succession. In this case the following procedure may be adopted as an example:—

A collodionised substratum is sprayed first with, say, a red coloured solution of caoutchouc (in chloroform), then with a blue coloured solution of gelatine, and the plate finally bathed in a solution of the third dyestuff (yellow-green).

The dyestuff migrates from the solutions of caoutchouc and gelatine into the collodion, and the caoutchouc and the gelatine are removed by washing, whereupon the substratum appears stained with the three colours. The third colour is not necessarily applied by bathing in a solution of the dyestuff, but may also be applied by spraying. By using dyestuff solutions that will not mix together they may all be applied at the same time by means of two or three spraying devices, as the case may be.

Another typical method consists in first covering a collodionised substratum, such, for instance, as film, glass, paper, etc., with figures (dots, for example), by any process, *e.g.*, by printing with colourless gelatine, this operation being performed in such a manner that the coated surface occupies one-half the total superficial area of the screen. Then regular figures (*e.g.*, dots) are applied cross-wise, so as to cover only one-third of the surface of the screen, by means, say, of a yellow-green varnish colour. Provided the figures or dots have been distributed with geometric uniformity, the two groups of figures or dots will overlap each other to an extent equal to one-sixth of the area of the screen. A collodion film prepared in this way is bathed for a short time in the above cited mixture, consisting of a solution of methylene blue and erythrosine. Since the fatty yellowish-green colour will not absorb any of the dyestuff solutions, only the parts left uncovered by the fatty colour, and consisting one-half of collodion and the other half of gelatine, will be stained. Since the gelatine is stained red and the collodion blue in such a mixture of dyestuffs, it is clear that a three-colour screen, free from imperfections of covering, can be obtained by this means. Separate baths of erythrosine and methylene blue, or similar dyestuffs, may be used instead of the mixed bath. Again, the fatty colour may be applied first, and a gelatine solution stained (red) with rhodamine may be applied over and partly covering it. In this case the red rhodamine migrates from the gelatine into the collodion, but it is not absorbed by the fatty colour. The free collodion is then stained by bathing in a solution of methylene blue or similar dyestuff, which is not absorbed either by the fatty colour (which will not take up any dyestuff at all), or by the gelatine. Both the stained gelatine over the parts in contact with the fatty colour and the gelatine from which the rhodamine has been absorbed by the underlying collodion, are then removed by a short bathing in lukewarm water, leaving a completed three-colour mosaic free from any imperfections of covering.

Another method of carrying out this process consists in the following:—Three filaments stained with different primary colours are prepared from stained solutions of gelatine or the like, and are made into a tissue or fabric; or three powders, made from differently coloured gelatine, are mixed together and pressed to form a block; or thin leaves of gelatine stained with different colours are laid alternately one upon another until a block of a certain thickness is obtained, this being then divided into two parts by a vertical cut. The fabric, or compressed or divided block, is used as a printing block, by being applied for a short time to the collodionised surface of the substratum, whereupon the adjacent and uniformly distributed dyestuffs in these blocks migrate into the collodion. These printing blocks may be used for the same purpose more than once, whilst any traces of gelatine adhering to the substratum after the impression may be removed by washing. If the substratum be gelatinised, then the printing blocks must be made of stained collodion, the dyestuffs used in this event being such as will migrate into gelatine.

In order, for optical reasons, to dispense with an insulating layer between the three-colour screen and the panchromatic emulsion, the screen stratum, on the surface of which the patches of colour are carried, must consist of some material other than that of the panchromatic stratum. If the panchromatic stratum be a gelatine-silver-bromide emulsion, the screen substratum must be made of collodion or caoutchouc, for instance; but if the panchromatic stratum consists of collodion or other substances, then the substratum carrying the screen must no longer be of collodion, but of some other material, such as gelatine. The inventor also refers to the use of paper for producing paper prints. Jan Szczepanik, Luisenhof, Weisser Hirsch, Dresden.

**COPIING SCREEN-PLATE COLOUR TRANSPARENCIES.**—No. 28,614. 1907. The invention relates to the use of the polychrome colour screen plates obtained by the section-cutting method, applied to a block formed of a series of superposed films or layers of coloured collodion or similar material. In using such plates, as in the case of plates of linear structure, it is proposed, in order to distribute the colour field of the screen uniformly, that the line screens of the negative and positive should be so arranged that their lines intersect each other at a right or at an oblique angle, whereby it is also made possible to make enlargements of the coloured screen negatives. The invention therefore consists in providing the negative and positive plates or supports with screens prepared by cutting section from compressed blocks of superposed foils of different colours, applying sensitised emulsion to such line screen-plates or supports, and arranging the second or positive line screen-plate with its lines intersecting the lines of the first or negative line screen-plate when exposing the positive screen-plate. The screens produced in this manner are preferably provided with a protective coating, for which it is best to use collodion or celluloid film. Arthur Schwarz, 27, Siemensstrasse, Steglitz, near Berlin.

The following complete specification, etc., is open to public inspection before acceptance under the Patents Act, 1901:—

**COLOUR STEREOSCOPY.**—No. 28,764. 1907. Apparatus for taking photographs in colours and causing them to appear stereoscopically. Geisler.

### New Trade Dames.

**CINE-PHONO.**—No. 304,769. Phonographic apparatus, other talking machines, and accessories included in Class 8 relating thereto; cinematographic apparatus, projecting lanterns, and accessories included in Class 8 relating thereto, including films included in Class 8; and synchronising apparatus included in Class 8 for simultaneously synchronising phonographs and cinematographs. Compagnie Générale de Phonographes, Cinématographes, and Appareils de Précision, 99, Rue de Richelieu, Paris, France, manufacturers. July 16, 1908.

**RAJAH COMPETITIONS.**—Messrs. Rajah, Ltd., send us a new circular relative to the monthly competition in which they offer a folding pocket camera, fitted with Beck-Steinheil  $f/6.3$  anastigmat, valued at £8 3s. 6d., for the best print or enlargement on any of the Rajah papers or postcards. There is only one condition—viz., the goods must be purchased from a photographic dealer. All prints, including winning prints, are returned if return postage is included.

## Analecta.

*Extracts from our weekly and monthly contemporaries.*

### A Useful Cement in the Studio.

The "Artura Bulletin" suggests that a cement made by fixing litharge with glycerine will be found very valuable for making nearly all kinds of repairs in the photographic studio, as it may be applied almost on any surface or material and, when thoroughly hardened, is practically water, acid and heat proof. The litharge should be added to the glycerine. For repairing broken graduates, porcelain trays, etc., it should be of the consistency of thick cream. The edges of the break should be pressed firmly together and allowed to set until thoroughly hardened, while for repairing large-size cracks in wood or metal dishes, it should be mixed considerably thicker, almost to the consistency of putty. There are a hundred and one instances in which this cement will be found to be exceedingly useful.

### Bromide Solution of Hypo-ferricyanide as a Reducer and Clearing Bath.

An editorial article in "Photo-Notes," dealing with the modification of the Farmer reducer, published by Mr. C. Welborne Piper in our issue of May 1, 1908, recommends the following formula:—

Hypo, 40 per cent. solution	...	2 ozs.
Potassium ferricyanide, 20 per cent. solution	...	2 drams.
Potassium bromide, 10 per cent. solution	...	2 drams.
Water	...	12 drams.
Ammonia (strong)	...	2 drops.

This is a strong reducer, and if a weaker one is desired the ferricyanide and bromide can be reduced to half quantities. It will be found that this reducer has a very marked effect on plates, and a plate that is slightly veiled is cleared very rapidly. Indeed, we use the reducer as a clearing solution for both negatives and lantern slides. For this purpose we fill a deep dish and after simply dipping the plate once or twice into the solution. After each dip it is rinsed under the tap and carefully examined to see if the effect is sufficient. Sometimes one dip alone is quite enough. The clearing is generally carried out after fixing, but before any washing. It can, of course, be done after washing, but a second washing becomes necessary. In any case no attempt should be made to either reduce or clear a half washed plate. If the film is either free from hypo or quite saturated with it then the operation may be carried out with safety, but if the hypo is only washed out, uneven markings are pretty sure to result. Yellow stain is often a trouble when Farmer's reducer has been applied to a plate for a long time, or when the same solution is used for several plates in succession. Quick action in a strong solution is the best preventive of this trouble, but the modified reducer recommended is much less prone to give it than the old formula.

### FORTHCOMING EXHIBITIONS.

December 11 to 14.—Cambridge and District Photographic Club. Sec., T. J. Sowdon, Sunny Side, Guest Road, Cambridge.  
 December 20.—Redhill and District Camera Club. Sec., J. Paterson, News House, Redhill.  
 December 23 to 26.—Lancaster Photographic Society. Entries close November 14. Sec., J. Holt, 11, Fern Bank, Lancaster.  
 December 9 to 12.—Bolton Amateur Photographic Society. Secs., A. N. H. Wylde and J. Bailey, 25, Croston Street, Bolton.  
 December, 1908, to January, 1909.—Kiew International Photographic. Sec., S. T. Horowitz, Technical Society, Kreshchatik, 10, Kiew, Russia.

1909.

January 6 to 27.—Northern Photographic (Manchester). Entries close December 11, 1908. Sec., S. L. Coulthurst, Broad Oak Road, Worsley, Manchester.

January 13 to March 13.—South London Photographic Society. Sec., H. Creighton Beckett, 44, Edith Road, Peckham, S.E.

## Dew Apparatus, &c.

A New Projection Arc Lamp. Sold by A. E. Staley and Co., 19, Thavies Inn, Holborn Circus, London, E.C.

A new automatic feed arc lamp, which should be very favourably received for enlarging and lantern purposes, has been introduced by Messrs. Staley and Co., at whose showrooms in Thavies Inn it can be seen working. The lamp is provided with magneto automatic adjustment, and certainly gives a most steady light, requiring no adjustment, and being brought into action simply by switching on the current. The mechanical construction of the lamp is of a very solid character, and rack adjustments, vertically, up and down, and sideways, are provided. The lamp is supplied for either direct or alternating current at the following prices:—

	£	s.	d.
6 ampères, 110 volt, direct current	4	5	0
6 ampères, 110 volt, alternating current	4	15	0
6 ampères, 220 volt, direct current	4	15	0
6 ampères, 220 volt, alternating current	5	5	0
15 ampères, 110 volt, direct current	5	15	0
15 ampères, 110 volt, alternating current	6	10	0
15 ampères, 220 volt, direct current	6	10	0
15 ampères, 220 volt, alternating current	7	5	0
30 ampères, 110 volt, direct current	12	10	0
30 ampères, 110 volt, alternating current	14	0	0
30 ampères, 220 volt, direct current	14	0	0
30 ampères, 220 volt, alternating current	15	10	0

## New Materials, &c.

Photo-Fans. Sold by J. Fallowfield, 145, Charing Cross Road, London, W.

Quite a novelty, which the firm of Fallowfield has just placed upon the market in time for photographers to make a Christmas specialty of it, is a hand-painted fan, measuring about 6 x 7 inches, and of the series of shapes shown in the illustration. The designs number six in all, each providing space for the attachment of a photograph, and

it is easy to see that a photographer might create new business in the use of these new introductions by offering them, not only as a form of portrait photograph, but also for the presentation of menu cards,

ball programmes, and similar articles which might be purchased in numbers for social functions. The fans retail at 6d. each, 5s. 6d. per dozen, or 60s. per gross.

**CALENDARS AND CHRISTMAS SEALS.**—The Crown Photographic Manufactory, Rotherham, send us samples of the attractive gilt mottoes and gummed seals, both devices of which good use may be made during the imminent Christmas season. The former are sold at 1s. 6d. the latter at 1s. per 100. The firm also supplies an inexpensive line in calendars in the shape of a mount  $6\frac{1}{2} \times 4$ , with space for circle print of  $2\frac{1}{2}$  in. diameter. The mount bears a calendar table for the year 1909, and is sold at 1s. per dozen.

### CATALOGUES AND TRADE NOTICES.

**SECOND-HAND LENSES AND CAMERAS.**—We are in receipt of a list just published by Mr. Arthur Spencer, 41, Harrow Road, London, W., in which is priced a very conveniently arranged selection of lenses, cameras, and other photographic apparatus. Mr. Spencer handles a large amount of apparatus, and we can vouch for the fair and business-like manner in which customers are treated. The present list is particularly strong in lenses, hand and stand cameras, all of which are classified and arranged in order of size.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

FRIDAY, NOVEMBER 13.

Birkenhead Photographic Association. "On the Printing, Developing and Toning of Velox Papers." W. F. Slater.

SUNDAY, NOVEMBER 15.

South London Photographic Society. Excursion to the City and Westminster. H. C. Beckett.

MONDAY, NOVEMBER 16.

Southampton Camera Club. "Making and Toning of Gaslight Lantern Slides." W. H. Trigg.

Acton and Chiswick Polytechnic Photographic Club. "On the Printing, Developing and Toning of Velox Papers." W. F. Slater.

Scarborough and District Photographic Society. "A Chat About Reptiles." W. J. Clarke, F.Z.S.

Bradford Photographic Society. "On the Fringe of the Austrian Alps." C. B. Howdill, A.R.I.B.A.

Kidderminster and District Photographic Society. "Photographic Lens Making." Taylor, Taylor and Hobson.

South London Photographic Society. 1908 Affiliation Prize Slides.

Stafford Photographic Society. Photography 1908 Prize Slides.

Catford and Forest Hill Photographic Society. Monthly Competitions. Criticism by W. Benington.

Rodley, Farsley, Calverley, and Bramley Photographic Society. "Enlargements." Messrs. Mellor and Hartley.

Lancaster Photographic Society. "The Causse." J. W. Pickard.

TUESDAY, NOVEMBER 17.

Royal Photographic Society. The 11th Traill-Taylor Memorial Lecture. "On the Regulation of the Rays in a Lens System." F. Wandersleb, Ph.D.

Halifax Camera Club. "Exhibition of Thornton-Pickard Prize Slides and Apparatus." R. Hesketh.

Leeds Photographic Society. "The Oil Process." Rev. Henry W. Dick.

Hackney Photographic Society. "Some Novel Lighting Effects." H. Essen-high Corke.

Hanley Photographic Society, Y.M.C.A. Photography Prize Slides.

Chiswick Camera Club. "Ancient Abbeys and Churches of Essex." C. Forbes.

Worthing Camera Club. "Enlarged Negative Making." J. F. W. Goodwin.

Wimbledon and District Camera Club. "On the Printing, Developing and Toning of Velox Papers." W. F. Slater.

Blackburn and District Camera Club. "Picture Making." Walter J. Pearse.

Epsom and District Literary and Scientific Society. "Flashlight Photography, Development, Rapid Fixing and After Treatment of the Negative." Chas. Zimmermann & Co.

WEDNESDAY, NOVEMBER 18.

Borough Polytechnic Photographic Society. Lantern Slide Competition.

Wimbledon Park Photographic Society. "Framing the Finished Picture by Means of a Passe-Partout Outfit." J. Adams.

L.C.C. School of Photo-Engraving, Bolt-Court. "Book Ornament." E. F. Strange.

Woodford Photographic Society. "On the Printing, Developing, and Toning of Velox Papers." W. F. Slater.

South Suburban Photographic Society. "Haunts, Habits and Homes of a Few Rare Birds." J. Cyril Crowley.

North Middlesex Photographic Society. "Enlarging." D. Fox.

Croydon Camera Club. "The Intensification of Negatives." Walter Wood.

Leeds Camera Club. "Some Dutch Places and People." Arthur Marshall, A.R.I.B.A.

THURSDAY, NOVEMBER 19.

London and Provincial Photographic Association. "Telephotography." Ernest Marriage.

Richmond Camera Club. "On the Printing, Developing, and Toning of Velox Papers." W. F. Slater.

Handsworth Photographic Society. Photography Prize Slides.

### ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held Tuesday, November 10. Mr. Frank P. Smith gave a lecture on "Flies and their Foes through Microscope and Camera," and employed both lantern and cinematograph to illustrate a most humorous lecture. The lecturer treated his subject in a manner calculated to both interest and amuse his audience, the cinematograph illustrations proving particularly entertaining, and the proceedings terminated with a hearty vote of thanks to Mr. Smith.

**THE PHOTOGRAPHIC CLUB.**—The annual general meeting was held in the club room, Red Cross Hotel, Paternoster Square, on Wednesday, the 4th inst., Mr. F. A. Bridge in the chair. The report of the committee and the balance-sheet were adopted. The election of the officers and committee for the ensuing year resulted as follows: Trustees: Messrs. F. A. Bridge and H. Snowden Ward. Committee: Messrs. R. R. Beard, D. Bradford, T. W. Derrington, G. Edey, Mackie, H. Muller, C. H. Skillman, W. Wiedhoff. Hon. Sec. and Treasurer: A. Corbett.

## Commercial & Legal Intelligence

**THE CANVASSING FRAUD IN DORSET.**—Lilian Welch, a married woman, living in Monmouth Road, had been sued, before the Dorchester County Court, by Allan Richard Macartney of Bridgwater, trading as the Modern Art Company, for 7s. 6d., balance of a charge of 12s. 6d. for the supply of an enlargement of a photograph of her husband, framed. Defendant's husband appeared on her behalf, and said that he wished to expose plaintiff's methods. A canvasser came round from house to house and offered to take any photograph and make an enlargement of it for nothing. Tempted by this offer people gave him photographs. The enlargements were made, and then plaintiff came round with them framed and asked 12s. 6d. for the framed production, the money being ostensibly for the frame. His wife was one of the victims. She had paid 5s., which she considered to be far more than the value of the frame, as the portrait could be framed quite as well in Dorchester for two or three shillings. After hearing the evidence the Judge dismissed the summons. Defendant then said that if plaintiff would give him back the five shillings which had already been paid he could take the framed portrait away.

**THE CANVASSING GAME AT BRENTFORD.**—At Brentford Police court last week, a charge of attempting to obtain 10s. 6d. by fraud from an Ealing servant girl against Adolph Breslaner, of Blenheim Crescent, Notting Hill, was heard. The girl was seen at the door of her house in an agitated condition talking to the prisoner. Sergeant Hambrook made inquiries, and the girl told him that a week or two young women called on her and asked her for a photograph, stating that they would give her an enlargement free, as they were opening a studio at Ealing. She gave them a photograph, and received a paper with the words, "Special offer, 10s. 6d." The prisoner then brought the enlargement and demanded 10s. 6d., when she refused to pay, told her she would be summoned. The girl, Heldmann discharged the prisoner, but added that there was no doubt that the girl foolishly believed the story of the women.

**BRISTON BANKRUPTCY.**—In a notice appearing under this heading in our issue of October 30 we regret that two figures were inadvertently transposed, the amount of the debtor's liabilities being given as £534 13s. 6d. instead of £354 13s. 6d., the latter being the correct amount.

**A GENERAL MEETING** of the members of the Art Photogravure Co. Ltd., is to be held at 113, Wool Exchange, London, on December 15, for the purpose of having an account laid before them showing in manner in which the winding-up has been conducted and the property of the company disposed of.

## News and Notes.

**NEWMAN AND GUARDIA, LTD.**—We learn that Mr. A. S. Newman is no longer connected with the firm of Newman and Guardia, Ltd., of which since the death of Mr. Guardia a little over two years ago he has been a director. Mr. Newman, it is hardly necessary to say, has for nearly twenty years past contributed his exceptional talents as a mechanic to the design and construction of the cameras and other instruments which under the name of "N. and G." have become not only famous but, it is not too much to say, hall-mark of quality and of punctilious workmanship.

The business of Messrs. Newman and Guardia, Ltd., will, we learn, be carried on as hitherto. In the manufacture and supervision of the standard "N. and G." instruments the firm will retain in their service those who have long been in their workshops, while the general management of the business remains in the hands of Mr. Frank Polwell. Patrons of the firm thus have the satisfaction of knowing that the high quality of the "N. and G." manufactures is to be maintained, and the supply of the standard instruments and accessories continued without interruption.

**CINEMATOGRAPH SCANDAL.**—A case of revolting cruelty to a horse was decided last week at Lorient against a cinematograph company which has made a specialty of reproducing dramatic scenes. The company accepted for production a scenario which included an episode of a runaway horse throwing itself over a precipice, and some employees of the company were instructed to obtain pictures of such a scene. The men harnessed a horse to a light cart, drove it towards the edge of a cliff 300 ft. high, and then flogged the animal until it dashed off in terror and threw itself over the cliff, while an operator cinematographed the scene. The photographer was acquitted, but the others concerned were fined 12s. each, that being the maximum penalty under French law for cruelty to animals. The company was ordered to pay costs.

**LOSS OF A CAMERA AT THE EXHIBITION.**—At Marylebone County Court on November 2, Mr. F. C. Becker, of the Odol Chemical Works, Southwark, S.E., sued the Franco-British Exhibition Co. for £4, the value of a camera which had been lost in the Exhibition. On May 23 Mr. Becker entered the Exhibition carrying a Kodak, and an attendant stopped him and said that he could not take the camera with him until he had a ticket to use it, adding that it would be quite safe if he left it with him. Mr. Becker handed the camera to the attendant, who deposited it in a side-room. He left the grounds by the Wood Lane exit, and when he applied for his camera it could not be found. Search was made, but with no satisfactory result. His Honour, in giving judgment for the defendants, said the plaintiff had not taken the precaution to see whether the attendant was authorised to take the camera, so he left it at his own risk. His Honour declined to give the defendants costs.

**THE "WORLD NUMBER"** (Welt-Nummer) of our contemporary, "Photographische Industrie," is a production in which our confrère, Herr K. Wolf-Czapek, has our congratulations. The issue for £4, the value of a camera which had been lost in the Exhibition. On May 23 Mr. Becker entered the Exhibition carrying a Kodak, and an attendant stopped him and said that he could not take the camera with him until he had a ticket to use it, adding that it would be quite safe if he left it with him. Mr. Becker handed the camera to the attendant, who deposited it in a side-room. He left the grounds by the Wood Lane exit, and when he applied for his camera it could not be found. Search was made, but with no satisfactory result. His Honour, in giving judgment for the defendants, said the plaintiff had not taken the precaution to see whether the attendant was authorised to take the camera, so he left it at his own risk. His Honour declined to give the defendants costs.

**A PHOTOGRAPHIC SOCIETY FOR GODALMING.**—A society has recently been formed for Godalming and district, membership of which is open to both ladies and gentlemen. The annual subscription has been fixed at 2s. 6d., and a syllabus, which will include lectures, demonstrations, outings, etc., is well understood in course of preparation. Those wishing to avail themselves of the advantages offered by such a society should communicate with the hon. secs., Messrs. S. R. Verstage and R. Steadman, Jun., Holloway Road, Godalming, who will be pleased to furnish full particulars on application.

**"TRAVEL AND EXPLORATION."**—On January 1, Messrs. Witherby and Co., 326, High Holborn, will issue a new monthly magazine under this title. The new periodical will be devoted to all aspects

of travel and will include such features as:—"Personal Narratives by well-known explorers in wild and little known parts of the world." "Colonisation and Travel on the Outskirts of the Empire." Articles by experts on "Where to Travel and What to Explore; How to Travel and What to Take." "New Highways for Travel, Yachting Trips, Extended Motor Tours, Balloon and Airship Journeys." "Biographies of Noted Travellers." "Literature of Travel." "Notes and News by Specialists." The price will be one shilling, and as the magazine will utilise photographic illustrations largely, it will undoubtedly interest many of our readers—some possibly in the way of providing a new outlet for the disposal of rights of reproduction.

**MR. F. H. STANDISH**, who has acquired the business carried on by Mr. W. C. R. Crooke, trading as the National Photo Co., at 152a, King Street, Hammersmith, applied to the local council for three months' renewal of the tenancy agreement which terminates shortly. Subject to certain conditions, the council has granted Mr. Standish the premises on a quarterly tenancy at a rental of £90 per annum. The council state that the tenant will not be entitled to claim any compensation in connection with the widening of King Street on the setting back of the premises let to him.

**L.C.C. PHOTOGRAPHIC RECORD.**—In July last the London County Council referred back a recommendation from the Records Committee that a water-colour drawing of the site of the new County Hall should be obtained. The Council invited the Committee to consider the advisability of providing a suitable photograph, and this week the Committee reported having, in accordance with the foregoing, arranged for photographs of the site to be taken from different positions and mounted on linen for the purposes of record.

## Correspondence.

- \* *Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

### LANTERN SLIDES AND BROMIDE PRINTS DIRECT IN THE CAMERA BY REVERSAL.

To the Editors.

Gentlemen,—In my letter to you on reversal there are two mistakes; one, a printer's error, instead of "reversal exposure" please read "increased exposure." The other, which Mr. Carnegie points out, is obvious. It is a transposition of sentences. Naturally, it should read: "That if the exposure has been through the glass, as in the Autochrome plate, the reversal is easier and more complete, the image being at the bottom of film, etc., and vice versa."—Yours truly,

Thornton Heath,

November 9, 1908.

E. FENSKE.

### CATCHING DRIP FROM BOTTLE NECKS.

To the Editors.

Gentlemen,—We have hit upon a method of obviating the objectionable drip which often runs down the label of a bottle after pouring. We had a difficulty in this respect with our "time" developer, and in many cases a drip from the neck of the bottle destroyed the lettering on the label, and even the reading thermometer, which indicates the time to develop at all temperatures. We have now quite cured this defect by a band of several thicknesses of blotting-paper round the neck, which absorbs the drip and does not allow it to reach the label. It is true it gives the bottle a "sore-throaty" appearance, but that is better than a slobbered pinafore, and all our developer is now sent out in this way.—Your truly,

Hereford,

November 9, 1908.

WATKINS METER CO.

### ACTION FOR RETURN OF DEPOSIT.

To the Editors.

Gentlemen,—We notice in your last issue a report of a case in which a Mr. Marsh is described as trading as the Record Photo Printing Co., of Monument Road, Birmingham. This description is incorrect,

inasmuch as the Record Photo Printing Co. is the property of the above company, and Mr. Marsh was not even a partner in it, but was in our employ on a salary and commission.

With regard to the complainant in the case, a Mr. E. Sims, Marsh had our permission to take him as a pupil, and we understand the salary Marsh offered him was conditionally that he obtained certain orders, and this salary to be paid out of Marsh's own commission, but Sims apparently found the work too heavy and backed out of it.

We think that it is only just your readers should understand the true state of affairs, and since Marsh is no longer in our employ, kindly dissociate all reports of this case with the Record Photo Printing Co., which has been in existence some twelve years.—Yours faithfully,

THE CAMERART Co. (per C. R. Sugden),  
Proprietors of the Record Photo Printing Co.

3, Cherry Street, Birmingham,  
November 9, 1908.

#### PHOTOGRAPHS IN RELIEF.

To the Editors.

Gentlemen,—As subscribers to the "B.J." we have read the article on page 828, "Photography in Relief," which will lead your readers astray. On page 257 of issue No. 2,290 and page 202 of No. 2,288 you have given a good account of our process and of what would happen if instructions in your last article were followed. Not only is the relief obtained by the known process which you describe extremely slight, but it is also absolutely wrong when printing is done from an ordinary negative. We have studied mixtures and processes specially for this purpose, and allowing of the production of reliefs exceeding 1 cm. in depth, and we have experimented with another process in order to obtain a negative the transparencies in which are proportional to the relief of the original (which no other process will give), which is in course of being patented, and the results of which have already proved excellent in practice. Results obtained by our system may be judged from the article in the last number of "Je sais tout," and other journals containing the account of Mr. Carlo Baese. We shall make a communication of this new process and of the results as soon as the necessary patents are concluded. In order to recall to your notice the English accounts of the process we mention "Photography," issue No. 832, page 345; "Process Photogram," No. 129, page 151; "Photographic Journal," August, 1904; and "Scientific American," January 1908, page 57.

FOTOSCULTURA BAESE.

3, Via Nazionale, Florence, Italy.

[It was not claimed for the process which we described in our issue of October 30 that it gave a facsimile reproduction of the relief in a natural object, but it is nevertheless a thoroughly practical process for the production of a considerable degree of relief, the distribution of which is, of course, dependent on the lighting of the subject. Our correspondents are doubtless aware that the method we described in a modified form was much used in the past for photo-mechanical purposes; also for the production of bas-relief medallions.—Eds. "B. J."]

#### PROFESSIONAL PHOTOGRAPHY IN BRITISH COLUMBIA.

To the Editors.

Gentlemen,—In your issue of August 28 there appeared an article entitled, "In the Land of Makeshift," from the pen of a contributor who signs himself "B.J.'ite in British Columbia." Whilst there is much to commend itself to the energetic photographer who is unwilling or cannot invest capital in his business, there are also one or two points in connection with this contribution which, I think, are liable to convey a wrong impression of the state of the profession in the province of British Columbia. In the first place, your editorial comment which prefaces this article might lead some of your readers to suppose that it is not possible to obtain high-class photographic materials in the province. As far as the city of Victoria is concerned this is not the case, as there are two good houses here which carry a full line of all the ordinary stock required by the professional or amateur photographer, and even if some exceptional article should be required it can readily be obtained from Seattle in two or three days' time.

As far as the city of Vancouver is concerned, which is the place from which your correspondent is apparently writing and is located, I should imagine that an even better state of affairs pertains,

although I cannot speak as specifically on this point from my own actual experience. However, Mr. Frank Butcher, who was out here a short time ago, could give you exact information on this point, and he will, I am sure, bear out the above remarks regarding the city of Victoria.

The very title of your article is calculated to be very misleading to those who have never travelled, as though it is perfectly true that your correspondent has, according to his own admission, been sufficiently ingenious to make use of "makeshifts," it is, as I have pointed out above, unnecessary to do so had he wished to call upon the stock houses and obtain his materials from them in the ordinary course of trade.

There unfortunately seems a tendency on the part of some Englishmen who come out to British Columbia and who do not allow themselves sufficient time to become acclimatised or to thoroughly understand the conditions of this country, to write to the papers in the Old Country, as witness the recent correspondence in the "Yorkshire Post," and to malign the whole province of British Columbia. This is, I need hardly say, unjust, and while I wish it to be clearly understood that I am sure your contributor cannot be classed in this category, yet, at the same time, I think a certain sentence in his article—i.e., "Here to-day, to-morrow—where?" coupled with your predatory remarks, is calculated to convey a wrong impression of the conditions prevailing in this province. It may interest you to know that in this city we have a very flourishing photographic society, several of the members of which do exceedingly good work, and the recent joint exhibition which they made at the Provincial Fair, which was held here last month, was an exceedingly creditable one. As the judge of the photographic sections at this Fair for the last two years, I can also assure you that the professional exhibits called forth most favourable commendation, and could not be turned out by anyone who had not been working in this line for quite a number of years.

As time goes on this happy state of affairs will no doubt show still further development; and, in conclusion, may I draw your attention to an article which appeared in "Photograms of the Year 1904," from the pen of Mr. H. Mortimer Lamb, entitled "Pictorial Photography in British Columbia," from which you will see that the work done here, even at that date, called forth both the favourable comment of this recognised critic as well as that of the editors of this standard publication.—Yours truly,

ARTHUR V. KENAH.

Law Chambers, Bastion Street, Victoria, B.C.

[Our correspondent reads into the article by "B.J.'ite" and into our introductory paragraph a meaning which is not in either of them. Our contributor did not state that it was not possible to get high-class apparatus; on the contrary, he stated that it was; but he counselled the policy of keeping equipment which, on account of its cost, must be taken to any new location the photographer may choose, at a minimum. And in view of the still active development of the country which is going on it is reasonable to assume that his judgment is worth more than that of an armchair critic.—Eds. "B. J."]

MIDLAND PHOTOGRAPHIC FEDERATION.—The report for the first year (1907-1908) states that at the present date the membership is 43, and there are only a few societies in the Midland area outside its ranks. This may be taken as a proof that the usefulness of such an association as this is generally recognised. The Council would like to urge all societies to be represented at Council meetings. This is most important, as it is the best means whereby intimate connection can be secured between the members of the societies composing the Federation. The lecture list has been largely drawn upon, forty lectures having been given before sixteen societies. The circulating portfolio and slides have been exhibited at most of the societies. On June 9 the first united excursion was held, Oxford being the place selected. Forty-two were present from eight societies. The Federation is much indebted to Mr. Reginald A. R. Bennett, M.A., of Oxford, for his kindness in meeting the party and facilitating arrangements. Council meetings have been held at Birmingham (2), Leicester, Derby, Handsworth. The first annual meeting was held in Birmingham, October 1908, and the following officers were elected:—President, Mr. Harold Baker (Birmingham); vice-presidents, Mr. G. Whitehouse (Birmingham), Mr. W. T. Mason (Leicester), Mr. C. Barrow Keene (Derby), Mr. A. E. Cope (Handsworth); treasurer, Mr. Arthur Black (Nottingham); secretary, Mr. Lewis Lloyd (Birmingham).

# Answers to Correspondents.

## PHOTOGRAPHS REGISTERED:—

South London Photographic Company, Limited, 129, Newington Causeway, London, S.E. Photograph of Ernest Barry. Two Photographs of Harry Blaxter, 82, Chapel Road, Rochdale, Lancashire. Photograph of Hansom Cob with Men Advertising Adolph's Dairy, Rochdale. Photograph of the Stockton-on-Tees Amateur Football Team, 1908. T. Shrubsole, 82, Chapel Road, Norwich, Norfolk. Photograph of the Norwich Musical Festival Band and Chorus. Laidlaw, 6, Gayfield Place, Edinburgh. Two Photographs of Dr. W. F. P. Higgins, Holyrood Street, Chard, Somerset. Photograph of St. Mary's Church, Chard, Men's Bible Class. Photograph taken at Corn Exchange, Chard, of Ancient Custom of letting Market Tolls of Chard Borough by Minnie Sand Glass. Davis, 18, Princes Street, Edinburgh. Photograph. Group, Executive Council, Scottish National Exhibition, Edinburgh, 1908. G. Skellman, 23, Uxbridge Road, Shepherd's Bush, London, W. Photograph of Miss M. Walker in Colleen Dress.

G. W.—You must be guided by the fact that you cannot take action for infringement done prior to registration. It is usual to accept double fees for photographs innocently reproduced without permission, but apparently the use in this case was not innocent. Perhaps if you intimate your intention to stick out for your rights they may make you an offer, but we advise you to make quite sure beforehand what your rights are.

DEVELOPER.—Please let me know which developer you consider best for focal-plane photography. Would you advise pyro-metol?—LONG READER.

It is one of the most suitable, and used, perhaps about equally, with pyro-ammonia and the softer working developers, such as sodinal, etc.

MATRICAL PHOTOGRAPHY.—Are there any objections to the taking of photographs in theatres during the performance, (a) for personal use only, (b) for subsequent publication?—A. W. BROWN.

It is entirely a matter for the management of the theatre, who have, in the case of some actors, to bear in mind the fact that they (the actors) may have agreements with photographers for the sole right of making portraits of them.

FRY GLASS.—I have a studio, which is covered on the top and sides with ground glass. The outside is all right, but the inside, which is the rough side, is very dirty and inclined to look smoky. This defies all efforts to come clean, and I have tried chemicals of various sorts, and now is the time we want all the light we can get. Will you kindly let me know what will answer the purpose?—ANXIOUS ONE.

We should advise you to thoroughly wet the glass with strong soda and water. Then, after a time, scrub it with a brush and soap and water, and finally rinse with clean water. It is possible that the glass itself has become discoloured. Some kinds of glass discolour with long continued exposure to light. When that is the case the only thing to be done is to replace it by new.

PRINT.—Would it be possible to restore the photograph enclosed? cannot tell what paper it is on, but think the faintness is due to under-printing or developing. It has not faded, but is the same as I received it, some seven or eight years ago.—E. P. CONWAY.  
Nothing whatever can be done in the way of improving the print. If you could get the loan of the negative it is possible you might be able to obtain a better print from it. The print has been returned to you.

HAIR.—We should esteem it a favour if you would kindly inform us a formula how to make up oxgall, as we are told this is the best stuff to use to clean plate-glass before squeegeeing on same. This pretty well prevents sticking, and gives a much better gloss.—MR. GEORGE LAWRENCE PUBLISHING COMPANY.

The preparation of oxgall, as supplied by the artists' colourmen, is a troublesome and very unpleasant operation, therefore we would recommend you to purchase it ready prepared. It is not expensive, and a little of it goes a very long way.

APPRENTICESHIP.—Being a constant reader of the "Journal," I should be much obliged if you would kindly give me a little information re the enclosed. My son was apprenticed to a firm of photographers for three years. He has now just a month to complete his apprenticeship. The agreement states that in return

for his services he was to be fully instructed in the business of a photographer and the "art of photography." I have just had an interview with his master, and asked him whether he was not going to instruct my son in the studio work, re lighting, etc. He declines to have anyone in there with him. I believe the operating-room plays an important part in the "art of photography." Is this the usual method that an apprentice is not allowed to be instructed in the studio work? If not, what remedy have I? Can I take action?—AGREEMENT.

Of course, studio work, lighting, posing, and dealing with sitters generally is what the apprentice should be taught, as it is one of the most important parts of the "business and art of photography." If the indenture is properly stamped you can proceed against the master for the return of the premium paid, if any, and for damages for the loss of the young fellow's time.

UNSCRUPULOUS BUSINESS.—I gave an order to a firm of postcard publishers for a series of postcards, the same to be reproduced with my name on and called the ——— Series. Same were duly delivered. I find since that this same firm has been supplying other people with these postcards, which bear my name. Have I any remedy? The views are not registered.—POSTCARD.

Yes, you have a remedy. You can obtain an injunction restraining further use being made of your negatives; also you can sue the firm for damages. Better put the matter in the hands of your solicitor without delay.

BOOK ON X-RAY WORK.—I have a 10in. coil and record X-ray tube and 12 volt accumulator. Will you kindly inform me in your "British Journal" the best focus for radiographing a knee or thick portion of body? The hand I can manage all right, but cannot get anything much on a Lumière negative, after giving two minutes exposure. Is there a book which would direct me?—C. D.

"Practical Radiography." By Ward and Isenthal. (Dawbarn and Ward, Ltd. 6s.).

CONRAD.—(1) "Photography in Colours," by R. Child Bayley, will give you a good account of most of the processes. (2) Autochromes you could get, but examples and apparatus for the other processes are difficult to obtain. (3) Certainly a prism can be used in conjunction with a projection lantern. (4) Yes, apply to Sanger-Shepherd and Co., Gray's Inn Passage, Holborn, London, W.C. (5) They do, if strongly illuminated.

DEVELOPER.—I shall be obliged if you can give me a good pyro-soda tank developer formula to take about 25 to 30 minutes for portrait work.—S.

Pyro 1 oz., potass metabisulphite 4 oz., water 10 oz. This is diluted at time of use to make A solution. B is—Soda sulphite 2 oz., soda carbonate cryst. 1 oz., water 20 oz. Developer—A 1 part, B 1 part, water 8 parts, for a time of development of thirty minutes at 60 to 65deg. F. But almost any developer can be used, and in any case the time must be tested for a given brand of plate.

JOS. FORREST.—1. See page 818 of the "Almanac." 2. Amidol is an excellent developer for bromide papers; for plates we should prefer others which keep better in solution. You do not say what special object you have in view, so we can scarcely advise you. 3. You had better give a trial to the process given by Mr. Carnegie in our issue of October 23, page 810. 4. There is no special book on professional tourist photography.

GREEN TONES.—I should be much obliged if you can give me a method for obtaining green tones on Aristo platino-collodio-chloride paper.—F. J. S.

We know of none, but there are several solutions sold for the purpose (e.g., by the Leto Co.) for bromide and gaslight prints.

C. C. S.—The photograph has the appearance of over-correction and too flat lighting. Evidently you need to control your lighting by cutting off a good deal of the light which now illuminates both sides of the face equally. Stamp for return of photograph was not enclosed.

OWNERSHIP OF NEGATIVES.—Two and a half years ago I left a studio, owing my landlord a few pounds in back rent. This, however, was paid shortly afterwards. I left a few hundred negatives at the studio, not thinking I should require them again, but now I find some of my old customers are inquiring about some of them for re-orders, and I wish to take them away. The landlord refuses to give them up, at least, the sons do, the original

landlord being dead. I may state that I did all the business, as regards paying the rent, etc., with the manager, who did everything on behalf of the landlord. He still remains. I was always under the impression that no one could claim your own negatives, or use them in any way, as they belong solely to the photographer who took them, provided, of course, that he does not sell them outright. Furthermore, are not the original sitters the part-owners of the individual negatives, as they have paid for the photographs in the first instance? And could I stop the sale, or in any way the free use of their own negatives? The manager referred to in this letter admits he does not know anything about the law, or holding of negatives, and, of course, not having anything to do with a photographic business, he is only using his own ideas in the matter. I shall be pleased to hear about this, so that I shall know how to act. He has an idea that they are valuable, but as far as he is concerned they are of no more value than ordinary glass. The studio was unoccupied until this summer, when a friend of mine took it on. Being a friend, he was quite willing for me to take the negatives away. Had it been a stranger, he would, no doubt, have used the negatives to fill up his showcase with samples, etc., and could, of course, have told his clients that he had taken them originally. That is the special reason why I wish to take them away.—W. H. S.

The negatives are certainly yours and you have a right to them. They are not the joint property of photographer and sitter, though the photographer must not make use of them without the sanction of the sitter. We presume the "Manager" referred to is an agent of the landlord, but except by legal restraint or a similar process in respect of debt he has no right to retain them, and a letter from your solicitor would, we should judge from the facts stated, induce him to give them up.

**FLASHLIGHT GROUP.**—I have to photograph a stage group of about twelve persons by flashlight. Would you tell me which is the best to use, magnesium ribbon or the powder with lamp? 2. Would one lamp be sufficient, and where would be the best place to stand the lamp? 3. What lamp do you recommend to use?—**FLASHLIGHT.**

Powder is the only practicable method. As you are evidently a stranger to flashlight work the best advice we can give you is to refer you to the book, "Magnesium Light Photography," by F. J. Mortimer (Dawbarn and Ward, 1s.), which gives very complete advice as to lighting. A very good lamp is supplied by Messrs. Chas. Zimmermann and Co.

**DEVELOPER.**—Have made developer as follows:—1 oz. hydroquinone, 1 oz. metol, 8 oz. carbonate of soda, 8 oz. sulphite soda, 80 grains potass. bromide. I dissolved metol in pint of boiling water and added other ingredients, making up to 80 oz. with cold water, but something has precipitated to bottom of bottle and will not dissolve. Where am I wrong?—**J. CUTLER.**

In using such hot water. There is no necessity to employ water more than just hot to the hand. Otherwise, the order of dissolving the ingredients is correct.

**AJAX.**—Certainly such originals can be restored. Apply to Mr. E. W. Foxlee, 22, Goldsmith Road, Acton, W.

**COPYRIGHT.**—1. I have been told that it is impossible to copyright photographs of Royalty, and should be glad if you would let me know if this is correct. 2. I am painting a picture of the King for which I am taking the particulars from several others. Shall I be infringing any copyright by reproducing same as photographs?—**ALBION.**

1. You are misinformed. The photographs of Royalty are subject to copyright like any others. 2. If you copy parts only of other copyright photographs of the King you will be infringing the copyright in them both by making the painting and afterwards reproducing it.

**W. E. CLINT.**—The firm is well known in Detroit, Mich., U.S.A., and this address should find them. We do not know if they have an English agent. Spooner's, corner of Southampton Street, Strand, might supply them.

**PRESERVING NEGATIVES.**—Thanks for your reply re "Preserving Negatives." I did not mean so much by way of varnishing as storing safely, and yet so as to be readily found. What negatives seem to suffer most from is damp in some form; if laid one

against the other on shelves, change of temperature induces condensation. This attacks the edges and gradually gets absorbed into the whole film, causing spots of mildew more or less marked. Old collodion negatives used to be stored in grooved boxes, but these occupy so much space that this is an item when you have several thousands.—**CLIMAX.**

The absorbent qualities of the films being inherent in the gelatin process, there is no other remedy that we know of than impermeable varnish, such as the Vanguard. We know no system of storing which will obviate the dangers of damp, but ventilation of the storage boxes or shelves should to some extent help you.

**A CASE OF AGREEMENT.**—Last May in answer to an advertisement my employer wrote and asked for my terms and salary required. I asked 30s., but he wrote and told me he preferred giving me a small salary and commission. So he wrote and offered me 20s. and a 10 per cent. commission on all takings. To which I wrote and accepted. He further stated it was a permanency, and that he was opening a branch studio to which I should also have commission on its takings as well. When I arrived there he asked me to take the 30s. the first month and he would stop commission the second month. When I asked him for the commission he told me he would give me 30s. and a 5 per cent. commission over £20 the month. This he did for two months and then he stopped commission. Then at the end of October he told me as business was not so brisk I had better find fresh employment, as after Christmas he could not keep me on. He did not open the branch at all. As there is a difference of between £16 and £18, which I should have had if he had stuck to the original agreement, the question is: Can I claim this amount from him, and can I claim any damages through his breaking his written word? I have his letters he wrote me, and a copy of the ones which I answered his, agreeing to his terms. I have been told I have absolutely no claim on him, as it was not a signed agreement, and others say, If I get his letters stamped it is as good as a signed agreement. As it may mean I cannot find employment in the winter, the money would help to get me over the bad season.—**DUN DOWN.**

As you seemed to have agreed to the different alterations in the arrangements we doubt if you can recover anything, except any commission that may be actually due to you. If you have a written agreement stamped now it will cost you £10, and that it is doubtful if it will be of any value, seeing that you agreed to the modifications since made. You should have had a written engagement for a definite time, and it should have borne a penny stamp, then you would not be in the position you are in now and find yourself.

**VELOX.**—If you must use gas, we advise you to pay a call to Tress Company, 4, Rathbone Place, W., where you can see suitable lamps, or can obtain printed particulars. But a gas lamp is not the best thing for groups.

**SNOW SCENES.**—One reason for the practice is the prolongation of the exposure without the necessity of stopping down; but even a winter landscape has colour in it, and the effects of shadows seem to be better brought out by cutting down much of the exposure of bluish light from the more open portions.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

Dr. H. E. Corke describes his experience with the new "Thames" one-exposure colour plate now upon the market. (P. 884.)

At the Croydon Camera Club last week Mr. T. K. Grant dealt with a number of points in the Autochrome process. (P. 895.)

Dr. G. Hauberrisser has found that the addition of a few drops of tribasic sodium phosphate solution to the developer (edinel or hydroquinone) used for gaslight prints, has the effect of preventing, throughout a series of prints, the good black tone which is obtained by either developer on the first time of using. (P. 887.)

Professor Namias lays stress on the advantage of first fixing prints which are to be toned in the combined bath. This method has the advantage of much greater regularity of action, greater permanence, and economy of gold. (P. 886.)

Some details in the making of negatives, and particularly in finishing them, which should assure their lasting indefinitely under reasonable conditions, are the subject of an editorial article on page 882.

The Professional Photographers' Association is taking up the question often in dispute between photographers and newspapers, namely, the reproduction of copyright photographs without the mutual permission of the photographer. (P. 881 and 895.)

The precautions which should not be ignored when working the Autochrome process during cold weather are dealt with in an article on page 883.

The Traill-Taylor memorial lecture was delivered on Tuesday evening last by Dr. E. Wandersleb. A brief report appears on page 894.

Folding reflex cameras and folding pocket cameras are among the subjects of the week. (P. 889.)

The painful experience (of a well-known worker) of retoucher's cramp is mentioned under "Correspondence" on page 898.

Mr. A. H. Blake suggests a club or portfolio for night photography. (P. 897.)

## EX CATHEDRA.

**The Queen's Photographs.** The album of reproductions of Queen Alexandra's photographs has been so instantaneously distributed throughout the kingdom that to offer a review of it would be quite superfluous. It suffices to say that the "production" of the volume is altogether worthy of the exalted rank of the author and her beneficent purpose. The personal and familiar inscriptions under the photographs complete the charm of this most interesting volume, which, besides benefiting the charities to which the profits of the publication are to go, should still more popularise the art of photography among the hundreds of thousands who will obtain the book. Moreover, Kodak, Ltd., are to be congratulated on the public acknowledgment, which figures prominently next the title-page, that the pictures were taken with a Kodak.

\* \* \*

**The Photographic Rag-Doll.** A novelty in the way of a photograph intended for Christmas presents is being offered to patrons of a fashionable studio in the shape of a doll of the "Teddy Bear" type bearing where the face of the animal should be a photograph of the sitter printed on or transferred to a fabric. The idea of a doll-facsimile of Mamma and Papa must surely tickle the fancy not only of the parents, but equally of the very juvenile son or daughter who both derives and creates an immense amount of fun by heaping endless indignities upon the unresisting effigy of his or her proud progenitors. Many other applications of this idea should suggest themselves to an ingenious mind, and though the forthcoming Christmas season is too close upon us for ideas to be put into practical shape this year, the opportunity for business in toy novelties into which the photograph enters should not be lost sight of.

\* \* \*

**The P.P.A. and Press Photographs.** It will be seen from the report of the committee meeting of the Professional Photographers' Association printed in another column that there is reasonable prospect of a working arrangement being come to between the Newspaper Society, representing the interests of the Press, and the P.P.A., representing the interests of photographers, with regard to some of those occurrences in the publication of photographs by the newspapers which frequently lead to unpleasantness and even more serious consequences. Undoubtedly there have been instances on both sides where injustice has been done, and the hard things each side says of the other probably balance each other. But it is time now that the attitude of mutual recrimination should be abandoned. The Press and photographers are dependent upon one another. Newspapers must have photographs, and it is the business of photographers to supply photographs, and, apart from the

unpleasantness of conducting business in an atmosphere of suspicion, the loss of time involved in settling disputes which are often quite petty in character is serious. Many of the most constantly recurring causes of friction are distinctly preventable, that is to say, they could not arise if there were an established custom with regard to them, and even more complicated matters might be so dealt with that, in default of a prearranged means of adjustment, a simpler, more expeditious, and less expensive method of settlement be provided than an appeal to law. The matter could not be in better hands. The Newspaper Society is fully representative of the business side of the Press, and the Professional Photographers' Association has so consistent a record of dealing with the greater questions that affect photographers with ability, and, withal, in a broad-minded spirit, that the interests of all concerned on the photographic side are assuredly in safe keeping.

\* \* \*

#### The Scottish Salon.

The arrangements for the forthcoming Salon at Wishaw proceed apace. The various committees have had frequent meetings. The Hanging Committee has drawn out a plan of campaign, and the Entertainment Committee has practically completed the programmes. True to the original ideal of the "Salon" to show what other folks were doing, the Council have invited "foreign" exhibits. A graceful tribute has been paid to the memory of the late Horsley Hinton in securing a collection of his works to represent England. Dr. Boon, Italy, has accepted the invitation of the Council to provide a "one-man" exhibition of his work. This exhibit, besides including some of the more celebrated of Dr. Boon's works, will contain a number of new pictures which he is preparing specially for "The Scottish." The entries close on December 7th, and already there is evidence of a big entry, some well-known workers having made great preparations.

\* \* \*

#### Long and Short Focus Lenses in the Reflex.

In our last issue we printed an address by Mr. J. F. Duthie, in which, amongst many useful hints on focal-plane work, we may note a very simple point that has probably escaped the notice of some users of reflex cameras. While long focus lenses are of extreme value, with the reflex it must not be forgotten that their use practically lengthens the exposure. In high-speed focal-plane work the exposures are not governed by the ordinary considerations of light, plate speed, etc. They are, in fact, exposures that the average exposure meter looks upon as impossible, for they have to be controlled simply by the speed of the moving object, or rather by the distance that the image of that object moves within a given

time. With a ten-inch lens the image will move twice as far in, say, 1-1,000th of a second, as it will with a five-inch lens, therefore with the longer focus lens exposure is equivalent so far as sharpness is concerned to 1-500th of a second with the short focus one. If 1-1,000 second gives enough light action to impress the plate, and at the same time secure a sharp image with the eight-inch lens, we can obtain a better result with the five-inch lens at the same aperture if we lower the speed to 1-500. The depth of focus is naturally greater, and we gain in light action. The value of long focus lenses is felt when working at moderate speeds, but at the highest speeds it is the short focus lenses that scores.

\* \* \*

#### Increasing Power of Limelight.

Mr. C. E. S. Phillips, in "Nature," draws attention to a very simple method of increasing the power of limelight, and an expedient may at times be very useful. He simply places an incandescent mantle over the lime. If the lime is turned regularly, as, of course, it should be in any circumstance, a very powerful light can be maintained for about a couple of hours. This may be a valuable idea for those who wish to show Autochromes with an ordinary limelight. Though, of course, neither the limelight nor the mantle give light of quite the right quality, yet the trouble of working at high intensity may be got over by using the two in combination.

#### THE DETERIORATION OF GELATINE NEGATIVES.

We very often have queries relating to the deterioration of negatives, and it is, of course, generally very difficult to answer them, the possible causes of deterioration being varied. It is often assumed that a negative should be indefinitely if varnished; but many of our queries relate to varnished negatives, and it is therefore evident that varnishing alone is not a perfect precaution. The object of varnishing is, of course, to prevent the access of moisture to the gelatine film, but a film dry enough to varnish may yet contain sufficient moisture to lead to future trouble, and we suspect that in a good many cases the moisture is thus sealed up. With shellac varnishes such a state of things can hardly exist, for the film must be heated before the varnish is applied; but with cold varnishes, such as celluloid, it is more than probable that many neglect the preliminary warming that is in all cases desirable. A certain amount of extra trouble is involved in the heating process, and when the varnish dries just as well with heat there is a great temptation to neglect it altogether. Still it should be obvious to everyone that varnishing only protect the image from moisture coming from the outside, and that it affords no security whatever if the

### THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1909.

Edited by GEORGE E. BROWN, F.I.C.

THE forty-eighth annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published on December 1. This year's ALMANAC reached a total of over 1,000 pages, and the entire edition of 25,000 copies was sold out immediately. Of no other photographic book ever issued can two such unique facts be recorded. The edition for 1909 will also consist of 25,000 copies.

The editorial article will deal very completely with the important subject of

#### REFLEX CAMERAS,

and the systematic review of the work of the year under the title "Epitome of Progress" will be a strong feature of the volume.

The lines followed in the previous editions of the

ALMANAC will be maintained in general, but in a number of particulars the arrangement of the volume for 1909 will be modified to make it more than ever the book of universal photographic reference.

The ALMANAC for 1909 will appeal to photographers the world over as a daily reference guide in practical work. The standard matter and formulæ will be revised and added to where necessary, and, wherever practicable, new features of an informative nature will be added.

NOTICE—IMPORTANT.—Our publishers ask us to inform agents that the issue of 25,000 copies is now almost booked, and, as a second edition will not be printed, those agents and dealers who have not yet sent in their orders are advised to do so without delay.

underneath is moist. In fact, all it does is to prevent that moisture from ever escaping.

Very often, when examining varnished negatives, we have noticed that the film is not completely covered. Portions of the gelatine are left unprotected. There is no need for this to be the case, and in a properly varnished negative the edges of the film should be as perfectly protected as the centre. To secure a perfect seal, it is not a bad plan to scrape away the film for an eighth of an inch all round the plate and then varnish right to the edge of the glass. A very suitable tool for the scraping operation is a one-eighth chisel with a piece of wood tied on to the side so as to project beyond the cutting edge and form a guard. This guard is pressed against the edge of the plate to prevent any side slip of the cutting edge, and the tool is very rapidly run round the margins. We always treat Autochromes in this way, and in the old frilling days, when even a dry film would sometimes curl off the plate, we found it an excellent safeguard. It protected the edges from atmospheric influences that tended to separate the films, and it will similarly serve to protect a dry plate from moisture that otherwise may creep under the protecting varnish.

Another method of securing a perfect protection is to varnish by dipping. We may take a lesson from modern painting methods. When the wagon-builder has got to the paint stage he simply dips the whole wagon complete into a huge paint-pot and then hangs it up to dry. This is a very quick method whether applied to painting wagons or varnishing negatives, and in the case of the latter, celluloid varnish lends itself admirably to the process. When dry, the varnish on the glass side is quite easily rubbed off. The varnish can be kept in one of the old vertical dipping troughs. The dried plate is placed on a glass tupper, dipped, and then set up to dry. Several plates can thus be varnished in the time required to do one by the ordinary method.

Even though a plate is properly dried and varnished, changes will occur if the film is contaminated with chemical matter. If not quite perfectly fixed or not properly washed double is pretty certain to be evident sooner or later, and very quickly if the varnish was applied to a damp film. I suspect that very often the effect that our correspondents describe as "mould" is really due to chemical changes in an unclean image. Possibly the negatives were made in cold weather and fixed in a cold bath. Photographers often fail to realise what a difference temperature makes to the fixing operation. Though ten minutes may be sufficient in warm weather, an hour may be barely enough in the winter if we follow the old rule to leave the plate in the bath for twice as long as the white silver compound takes to disappear. Washing is, of course, very often imperfect. We have heard photographers refer with pride to the fact that they never washed negatives for more than ten minutes. On the other hand, we have known others to be equally proud, though with equally small reason, of the fact that they always wash negatives all night, which means, we may suppose, eight hours washing or more. As a matter of fact, while ten minutes is rather a short time in any case, yet a negative properly washed for that time may last much better than one that is over-washed. Over-washing tends to make the gelatine thin, and this is probably a more serious defect than the presence of a very minute trace of simple hypo.

An over-washed negative may easily become mouldy if left before varnishing. A good preventive is formalin, for if the gelatine has been sterilised by a formalin bath there is little probability of moulds forming in the varnished film. Heat may also serve as a sterilising agent. While formalin is a preventive, the other hardening agent, alum, so often used, may be the introducer of moulds.

An alum solution that has been made some time nearly always contains moulds, even though they may not be visible in the big clots that are so familiar. As a medium for introducing mould into gelatine, few things can be more effective than alum, but this is a risk that most photographers seem to have overlooked. Alum seems to be looked upon as a kind of fetish by some people; but while it does not do many of the things that are put to its credit, it is capable of causing serious trouble, therefore we always look upon it with suspicion. If alum is carefully avoided and negatives are treated instead with formalin and afterwards carefully varnished, any trouble from mould should be next to impossible.

To sum up—the procedure that we consider most certain to produce lasting negatives is: First, to make sure that fixing is complete; next to wash thoroughly, but not too long; then to formalin the negative, rinse and dry it; and, finally, to drive out all moisture from the gelatine by the agency of heat immediately before varnishing. It is difficult to see how a negative finished off with these precautions can possibly deteriorate if kept in ordinary conditions. We may add that the effectiveness of any method of varnishing can be readily tested by applying it to a waste negative, which is then put to soak in water for a few minutes. If the protection is perfect the gelatine should be unaffected.

#### CARBON PRINTING IN WINTER.

THE recent sharp touch of cold weather certainly lends colour to the forecasts of the prophets who have predicted that the approaching winter may be one of unusual severity, and the fact may therefore be expected to give rise, among other forms of distress, to the usual epidemic of articles upon the effect of a diminished temperature on photographic procedure. The effects of cold weather upon the development of plates and the toning and other treatments of prints are probably by this time so well worn a theme that it is unnecessary for us to enlarge upon it, but we may usefully have something to say on the effect of the same causes in the use of carbon tissue, a printing process which is more markedly affected in this way than is silver or platinum, but which nevertheless continues to grow in favour of both amateur and professional.

It should first be mentioned that the process of carbon printing is affected by variations in the temperature largely because the tissue is susceptible to the variations (concomitant with temperature) in the hygroscopic condition of the materials and of the air. Working under conditions which are alike in all else save only temperature, it will be found that exposure has to be much prolonged in order to obtain results similar to those obtained in the summer, quite apart from the difference in the actinic quality of the light. The gelatine of the tissue absorbs water or aqueous solutions more quickly when the temperature is high than when it is low, and consequently if the tissue is immersed, we will say, in  $3\frac{1}{2}$  per cent. solution of potassium bichromate for the time usually adopted—say three minutes at a temperature of 40 to 50 deg. F.—it will absorb much less of it than it would at a temperature of 60 to 70 deg. F. Hence the tissue is less sensitive, and unless this fact is realised and allowed for, errors in the exposure may occur, and the actual cause not be suspected. Particularly may this be the case if, as is the case with many workers of the process, the negatives be marked with the number of tints of the actinometer which previous trials have shown to be right in exposing the prints, which figures were very likely obtained at a different season of the year.

To equalise these altered conditions several methods are

available. First, the temperature of the sensitising solutions may be raised to the normal of 60 to 65 deg. F., and the usual time of immersion continued; or, by increasing the strength of the solution to  $4\frac{1}{2}$  or 5 per cent., a similar allowance may be made; or, lastly, the tissue may be immersed in the solution of the normal strength at the lower temperature for a greater length of time, say five instead of three minutes. Either of these methods will give us approximately tissue of the standard properties as regards speed, etc.

To pass now to a variation in the carbon process which is dependent, not upon the state of the atmosphere, but upon the value of the light, it is not fully realised by many that tissue is relatively much slower in printing in a dull and feeble light than in the strong light of summer, whilst the silver paper used in actinometers is not so influenced. The rapidity of the latter in darkening is proportionately about the same in lights of all strengths, but as an example of the difference in carbon tissue in this respect the following experiment is instructive:—If two carbon prints from the same negative and on similar tissue be printed (by actinometer), the one in bright sunlight and the other in a weak and feeble light, there will be a considerable difference in the depth of the two prints, that exposed to the feeble light being distinctly less printed than the other. It may be necessary in a very dull light to increase the exposure as gauged by the actinometer from, say, four to five or even to six tints, to obtain equal results.

It should be mentioned, also, that the dryness or dampness of the tissue affects its sensitiveness. When containing, as it usually does when dried in dampish weather, a fair amount of moisture, its sensitiveness is enhanced, while if it is abnormally dry, as it may be during very frosty weather, it becomes slow in printing. It is, of course, a well-known fact that when tissue is completely desiccated it becomes comparatively insensitive to light, and to this effect—which may result from severe frosty weather—must be added the other, that the extreme dry-

ness of the tissue may cause it to become so brittle as to make it difficult to handle without its cracking.

The hygroscopic condition of the tissue also affects the well-known property termed "the continuing action of light." If the printing has been done out of doors and the tissue be then brought into a warm apartment moisture will be deposited upon it, and it will thereby be quickly absorbed by the gelatine. Should the print be stored in a warm place for an hour or two before development, it will be found to have increased in depth to a considerable extent, whereas had it been changed into a cold place, it would have escaped the dampening process, and would have suffered little or no change during its subsequent storage. Exposed prints which are freed from moisture may be kept for months without thus "continuing," whereas the action is very rapid in the case of those containing moisture, and at the same time kept in a warm atmosphere.

It is pretty certain that tissue sensitised at home and dried under favourable conditions usually works better after keeping for a day or two. In winter it will be found that to bring tissue in the corresponding best condition it has to be kept for considerably longer: which amounts to the same thing as saying that the keeping properties of the tissue are much better in winter than in summer. In the hot season tissue will usually not keep more than three or four days under ordinary conditions of storage, or for a week or ten days if sensitised in the making. In the winter it remains in good condition for twice or thrice these times.

In conclusion, it may be mentioned that in mounting the exposed tissue on its support for development it will be found that in winter a longer soaking in the cold water is necessary in order to bring it into the proper condition. This will also be the case with the single transfer paper, and if transfer paper of rough surface and thick substance be employed, the soaking in water should be very greatly prolonged, or better still, the water raised to the temperature of 70 to 75 deg. F.

## THE "THAMES" ONE-EXPOSURE COLOUR PLATE.

As many photographers will during the next few weeks probably be making their first trials of colour photography by means of the new "Thames" colour plates, the following notes will perhaps interest them. This record of experience is written from a purely disinterested and practical point of view, the writer simply having bought the plates in the usual manner from a dealer. It is not proposed in the present article to actually make comparisons as to the merits or colour values of the two processes, as the "Thames" is practically a perfectly new manufacture, and I believe that the makers themselves actually admit that further improvements are possible, and are being made as quickly as they can. At present the "Thames" process certainly has its shortcomings, just as the early batches of Autochromes had their own drawbacks, such as a great tendency to frill and the presence of black spots in the colour screen, both of which were freely admitted by Messrs. Lumière at the time, and have since been removed from their wonderful product.

### A Separate Screen-Plate.

In the "Thames" plate the old theory of all one-plate colour processes is adopted, that is to say that the three primary colours, blue-violet, orange, and green, are distributed in their correct proportions upon a glass plate through which the photograph is taken, through which glass the finished results must also be viewed. But whereas Messrs. Lumière spread their

colours quite indiscriminately over the plate and in no regular order, the Thames Plate Co. apply theirs in a perfectly geometrical pattern. This distribution of the colours, and also the fact that an Autochrome plate consists of one piece of glass only, whilst a "Thames" consists of two glasses, one the colour screen and the other the sensitive plate, are the two chief differences between the two processes. The purchase of a box of Autochromes gives us four plates, each plate consisting of a piece of glass coated, first, with the starch colour grains, and directly on top of this with the photographic emulsion. In the case of the "Thames" plates we obtain two separate boxes, one containing two pieces of glass coated with the colour (the colour screens), and the other containing four colour sensitive gelatine dry plates.

To use the plates, we first place one of the colour-screens in the dark slide, glass side towards the lens, and then place one of the dry plates in contact, film to film, with the colour screen, finally placing a piece of black card on top of the dry plate. The exposure is then made, using a special colour filter just as in the Autochrome process. The dry plate is then developed, reversed, and finished in the ordinary way, and, of course, during all the processes looks just like an ordinary monochrome plate. When perfectly dry, it is again placed in register with the original colour-screen, when all the colours of the object photographed will be rendered. The correct registration is not at all a difficult process. It will

probably be found that at first when the plate and screen are in contact we obtain a curious and very pretty prismatic colouring over the whole plate which alters its pattern from a fine grid to diagonal lines, according to the way we move the plates in relation to each other. The plates are moved in opposite diagonal directions until the whole image is obtained, either as a monochrome, or every one of the colours, either correct or complementary. The very smallest movement in a perfectly upright or perfectly horizontal position will then bring all the colours correct. This registration is a fascinating process, and gives one a valuable lesson in the values of the various colours.

The fact that the colour-screens are separate from our photographic plate means that if by an error of judgment in exposure or development we are not at first successful we waste only the dry plate, and can use the colour-screen again to get a better result.

Another difference in which the "Thames" has an advantage is that the film is nothing more than an ordinary gelatine emulsion, and will stand much rough usage, so that no more than the usual care need be taken. Again, being a thicker emulsion,

Autochrome.

"Thames" allows of more latitude both in exposure and finishing.

#### Speed and Structure of the "Thames" Plate.

The speed of a "Thames" plate is stated to be much faster than the Autochrome, the makers giving it as H. and D. 12 when the compensating filter is in position. In practice I find that a subject requiring four minutes in "Autochrome" requires one minute in "Thames."

The difference in the actual size of the grains of an Autochrome and the dots of a "Thames" is very great. In actual fact under a microscope, I find that there are just about 12 red "Thames" dots to a linear one-eighth inch; this gives 19,200 dots per square inch. Squaring this, we thus find 6,400 dots per square inch. As there are exactly the same number of green as of red dots, we then find there are 12,800 dots, red and green, per square inch. The violet interspaces, though not actually the same shape or size as the red and green dots, must be of the same area, so, if we consider them also 6,400, we get a total number of 19,200 "Thames" dots per square inch.

Now, by placing a "Thames" plate in contact with an Autochrome under a powerful microscope, the comparatively large dots of the "Thames" will allow the smaller grains of the Autochrome to pass the light through. That is to say that, through the red dot of the "Thames" we shall see only the red grains of the "Autochrome," and in actual count I find an average of 27 "Auto-

chrome" grains of each colour to each "Thames" dot. Thus we estimate that the total number of red, blue, and green grains upon an "Autochrome" is 1,536,000, compared with 19,200 dots on a "Thames"; or, in other words, the "Thames" plate is eighty times coarser than the "Autochrome."

One would imagine from this that a "Thames" plate would look very coarse, but in actual work it does not. It looks just about the same as a half-tone picture such as we see in illustrations in the press. For lantern work "Thames" plates are not so satisfactory, as upon the screen the enlarged grain does show.

The photographic part of the working of a "Thames" is very much the same as for "Autochromes." The plate is taken from the slide in perfect darkness, and developed for three minutes in a two-solution developer consisting of hydroquinone and caustic soda, after which it is washed for one minute in water, and placed for one minute in a 10 per cent. solution of ammonium persulphate, and then again washed. This ammonium persulphate bath must be used fresh, otherwise the plate will fog and be quite spoilt afterwards.

The plate is then placed in an acid permanganate bath, and

[Thames, same magnification.]

we can open the window while the permanganate reverses the image, just as we do for Autochromes.

#### Reversal and Redevelopment.

The reversal takes about four minutes. This time is longer than the one minute usually recommended for "Autochromes" on account of the extra thickness of the emulsion. The plate is again well washed for four or five minutes, to remove the permanganate stain, and placed in an amidol solution to re-develop. We do not re-develop for a fixed time, as for "Autochromes," but just until the positive image looks dense enough, bearing in mind that the next operation, "fixing," will lessen the density considerably. There is no intensification for the "Thames" as there is for "Autochromes." The plate is washed, and fixed in an ordinary hypo solution. Whereas in an "Autochrome" there seems very little silver left in the plate by the time we reach this stage, yet the "Thames" will look just about like an ordinary plate with a decidedly creamy appearance, which takes about five or seven minutes to clear in the hypo. The plate is well washed, as usual for ordinary plates, and put up to dry. Drying may be expedited by giving the plate about five minutes in a bath of pure methylated spirits, after which it may be dried by gentle heat. We can then proceed with the registration and binding of the plate and colour-screen in the manner I have described.

Just a few words in conclusion as to the results I have obtained. The greatest fault at present seems to be that the makers are not quite perfect in the manufacture of the very delicately made screens. These screens are not yet perfectly

evenly coated, some I have had having a tendency to too much red, and some to too much blue. In one respect this does not matter so much, as, if we find that our finished results when bound with one of the bluish-coloured screens is rather too blue, we can simply use the redder screen, and this will to a great extent correct our colours. As the results are rather more dense than Autochromes, they appear much better when viewed by a strong artificial light, and also, as there seems to be usually not quite enough yellow, this artificial light should be a yellow light, such as incandescent gas, as it will just add sufficient yellow to make what are probably by daylight "blue-greens" into the correct greens.

When one considers the microscopic size of even the coats of the "Thames," one cannot be surprised that the maker find it difficult to obtain perfectly correct screens at present, but no doubt as time goes on and they are able to improve the method of manufacture they will correct this. The "Thames" is certainly an exceedingly interesting process, and the results personally give me much pleasure. Those who give it a trial, even if they do not get results quite so true as "Autochromes" will, I think, not regret the small expense they have incurred and will be interested to make personal tests between the two first direct colour processes which have ever reached the commercial stage.

H. ESSENHUGH CORKE.

## FIXING P.O.P. PRINTS BEFORE TONING IN THE COMBINED BATH.

[The fixation of prints prior to toning has frequently been advised, is theoretically an advisable course, and is, moreover, one which we believe is used in commercial work with success and economy. The following article, from Eder's "Jahrbuch," contains the recommendations of Professor Namias for working the methods.—Eds. "B.J."]

THE use of the combined bath, as it is ordinarily practised, frequently leads to more or less rapid alteration of the prints, and not infrequently to stained or yellowed prints. The latter defect is particularly marked in the case of baths which have been much in use. In all combined baths, which contain both lead and gold salts, the much admired black tone can be obtained, and the production of this tone is ascribed to the presence of the lead salts. A series of experiments have been made by the author as to the conditions which must prevail in order to obtain the best and most permanent results with the combined bath. The result has been to show that regularly good tones are obtained with combined baths, but that still more permanent results are produced if the prints are first fixed before going into the combined bath. This process avoids the majority of the evils which attach to the use of the combined bath pure and simple; and, though it may be urged against such a method that it destroys one of the chief advantages of the combined bath, namely, its simplicity in use, yet the difference is more apparent than real. The author finds that the fixing bath containing boric acid, worked out by him some years ago for the fixation of plates, is very suitable for this particular purpose, since the prints need only be drained from it, and may then be transferred direct into the combined bath without washing.

A suitable strength of bath is 30 to 40 per cent. This has no pronounced weakening effect upon the image of a good P.O.P. print, if used for the time 3 to 4 minutes, which is fully sufficient for the fixing process, or, rather, it has no greater effect upon the print than has the use of the combined bath in the ordinary way. The fixing bath contains 5 to 6 per cent. of boric acid, and it may be employed for the fixation of P.O.P. prints irrespective of the fact that it may previously have been in use for plates or bromide papers, though it should be free from all colour, a change which takes place in a boric acid fixing bath only after a very considerable time. A working formula for the bath will therefore be as follows:—

Hypo .....	6 ozs.
Boric acid .....	1 oz.
Water to .....	20 ozs.

The combined bath, it must not be forgotten, alters in its behaviour after use. In a new bath any sulphurising action is entirely due to the lead hyposulphite in the bath, which compound deposits most readily upon an image containing sulphide of lead. In an old bath there is present, in addition to the lead hyposulphite, silver hyposulphite, the quantity of which gradually increases with the use of the bath. The silver hyposulphite is a compound most prejudicial to the prints, inasmuch as active sulphur toning may occur, not only through the agency of the

lead sulphide, but chiefly through that of the silver sulphide. This produces a distinct liability to change in prints made on printing-out paper as distinguished from those on development paper.

Yet among both professional and amateur photographers is not uncommon to find combined baths being employed, the score of economy, which no longer possess the necessary speed of fixation, since they contain too much silver hyposulphite. In such conditions the print may show signs of alteration immediately after drying, inasmuch as there is not sufficient sodium hyposulphite present to remove the silver hyposulphite in the paper, and it is not too much to say that these are the conditions under which the combined bath is very often employed. In the case of prints which have been previously fixed the toning takes place somewhat more slowly in the combined bath, but without any disturbing action whatever. The bath works with great regularity, and it is only necessary to add a small quantity of gold chloride solution from time to time in order to obtain a full toning action. The silver which finds its way into the bath is so small in quantity that it does not begin to affect the action of the bath until after the toning of several hundred prints, whilst, in the case of the ordinary procedure, its effect is noticeable after a few dozen prints have been toned. For this reason the bath keeps much better, does not darken as when employed in the usual way, and is not quickly exhausted of its gold.

The writer has found that a print treated in the combined bath after previous fixing, and exposed to air and sunlight for a long time, did not show the slightest alteration, whilst a print toned in a combined bath containing an equal proportion of gold and otherwise treated similarly speedily faded. It was also noticed that a print previously fixed and then treated in a bath of hypo and lead salt only was equally permanent, although the tone was not so good. Further, the above method in no way affects the production of the regular black tone, which is the reason of the popularity of the combined bath among amateur workers, whilst it is, of course, far superior to the methods of separate toning and fixing, where the slightest trace of hypo in the toning bath gives rise to spots and stains.

Finally, it should be remarked that separate toning and fixing is more expensive, as the black tones must be obtained solely with gold. The foregoing results, therefore, should encourage photographers to employ this modified procedure of toning prints on printing-out paper, as apart from the production of more permanent results, it has the advantage of economy in gold, and the fixing process is quite without effect upon the treatment in the combined bath, so that the toning process can be stopped at any desired stage.

R. NAMIAS.

## DUDLEY HOYT'S METHOD OF STUDIO-LIGHTING.

[Mr. Dudley Hoyt, of Rochester, New York State, being one of the most accomplished and individual photographers, particularly of women sitters, it is interesting to find him in the current issue of "Photo-Era" explaining the principles which he has found most advisable in the portraiture of the richly dressed ladies who form the greater proportion of his patrons. The illustration which appears with this article is redrawn from a half-tone reproduction showing the actual arrangement of the studio.—Eds. "B.J."]

As I told Papa Cramer at the Detroit Convention, the plate is the daredevil which is backed by less confidence than any other medium in the practice of photography yet is, at the same time, a scientifically prepared product subject to our command. The fact is, I am inclined to believe that the photographer expects too much from his plate, and that he is not altogether in sympathy with its limitations, nor friendly towards its possibilities, judging from the many questions the studio and chemical demonstrations at Detroit called forth. The one thing the National Association did accomplish, as never before, was to encourage the photographer to ask questions which, when well answered, led back to the making of the negative.

In portraiture and its technical advancement there is a condition which we will have to face seriously in the near future—

that is, to keep abreast with the progress made by the manufacturers of colour-sensitive plates. In this way the judging of the relative values of light and shade will not be based entirely upon the different degrees of intensity of the direct or reflected light, but rather upon the chemical value of the separated colour of white light, composed of blue, green, and red, by which the best plates are tested and corrected. For instance, a red-blind plate, one sensitive to the yellow and green, will record in the negative a green of a very much lighter colour,

which will bring the yellow and green into very close relation in regard to tonal value, but entirely out of harmony with the lighting one saw and expected to obtain in the negative.

To light the model is not a difficult undertaking, provided one have a properly corrected plate to record the colour-values. If we bring to mind how intensely yellow the face of our model will appear when located some distance from the light, we realise the importance of the blue or violet in direct, white light. Bearing this in mind, we place the model in the direct light, the volume of which matters but little so long as there is a good blaze of direct, white light. The effect of the light is strong and contrasty, but can be reduced by the aid of screens to intercept a portion and to break the direction of the light. In changing the direction of the light and the reflecting of another portion, the white light has changed colour on different parts of the model—in other words, the light has separated into blue, green and red, and the tonal values are particularly flat and creamy.

We have noted in colour-photography that the absence of blue from white light reflects yellow formed by the union of red and green. With the use of this combination in the making of our negatives one can readily see that a negative with all the necessary brilliancy, fullness, and delicacy of detail, and of unusual quality, can be produced from an image which is apparently flat, but richly modelled. Its colour and vigour are dependent only upon the amount of white or direct light allowed to reach the portions of the figure which are most important.

This arrangement offers many advantages, especially when the photographer has but a small amount of light at his command. The light may then be thrown back and forth with screens, while the model takes on a very luminous tone of yellow, which is instantly relieved and modelled by a ray of direct light projected at the proper angle so as to touch up and bring into relief those portions of the model which need accentuating.

In thus touching upon the values of light and shade, I hope to have covered, in a brief way, a point which has been suggested by questions from many workers as to how they can best handle local conditions. As most photographers have some direct source of light, it remains for them to take into consideration the value of its proper distribution, and, after a series of experiments, they will find a key which best suits their requirements.

DUDLEY HOYT.

## ON OBTAINING PRINTS OF REGULAR BLACK TONE ON GASLIGHT PAPER.

[Avoidance of the deterioration of colour in gaslight prints is the subject of the following contribution to "Eder's Jahrbuch," by Dr. G. Hauberrisser, who finds a solution of sodium tribasic phosphate to be effective in preventing the

The so-called gaslight papers, which have during the past few years obtained such vogue that they have almost displaced bromide paper for contact work, possess the drawback that in making a number it is usually found that the pure black tone obtained on the first print or two gradually deteriorates as further paper is developed in the same solution. The tone becomes brownish or greenish, and more un-

satisfactory in this respect the greater number of prints which are treated in the same solution. In order to arrive at a working method for the production of black tones without the necessity of frequently renewing the developer, I have undertaken a series of experiments, first of all with the object of ascertaining the cause of the defect, and secondly, of discovering means of remedying it. All the experiments described below

were made with Tula gaslight paper from one and the same batch of emulsion, and all the prints were made from the same negative.

**Experiment A.**—In order to ascertain the effect of potassium bromide upon a fresh unused developer, six Tula prints were developed with the edinol "Special" developer, prepared by diluting 10 ccs. of this latter solution to 90 ccs. with water, and adding 10 ccs. 30 per cent. potassium carbonate solution, making 100 ccs. in all. This was mixed fresh for each Tula print, and was modified for each succeeding print by the addition of 10 per cent. potassium bromide solution to the amounts of 4, 8, 16, 32, and 64 drops, each of which restrained developers was employed, as also was one containing no bromide at all. This latter developer, and that containing only 4 drops of the bromide solution, produced a pure black, but with further addition of bromide a distinct greenish tone was obtained.

**Experiment B.**—Employing the above edinol developer (without bromide) 25 prints, 9 x 12 cm., on Tula paper were developed in one and the same quantity of solution, one after the other, i.e., about 25 quarter-plate prints in  $\frac{3}{4}$  oz. developer. The colour of the first four was pure black, but succeeding prints gradually showed the disagreeable greenish colour.

**Experiment C.**—This was a repetition of A, using, however, metol-hydroquinone developer; the results obtained were similar to those described in A.

**Experiment D** was a repetition of B, using metol-hydroquinone developer, and was attended with the same result.

On comparing the results of the different series of tests it was seen that in order to obtain pure black tones, fresh developer must be mixed up after four prints have been done, although, so far as concerns the detail in the prints, and disregarding the precise colour of the silver image, 25 and more prints may be successfully developed in this quantity of solution. The cause for the unpleasant tone is no doubt the introduction into the developer of potassium bromide, as shown by the A series of experiments. It was ascertained by analysis that the quantities of potassium bromide in an edinol "Special" developer in which 25 Tula prints of 9 x 12 cm. size had been developed, and in a metol-hydroquinone developer which had been used to develop the same number of prints, amounted respectively to .21 and .19 gm. As 64 drops of 10 per cent. potassium bromide solution amounts to approximately 5.5 ccs.—that is to say, to .55 of potassium bromide—and as, further, the greenish colour obtained in experiment A6 with 64 drops of potassium bromide was far less objectionable in spite of the threefold proportion of bromide than that in the last prints of experiments C and D, but about comparable with the tenth print (equivalent to a proportion of potassium bromide of about .08 gm.), it appears that the proportion of potassium bromide is not the chief cause of the defect in the tone. Further, as the strength of the developer is only very little weakened by its use for the 25 prints, it seems likely that by suitable addition to the developer a large number of prints of pure black tone should be developed.

After trials of a variety of substances I found that success was obtained in this direction by using tribasic sodium phosphate. Mixing up a 10 per cent. solution of this compound, 5 drops were added to the developer before the development of a fresh print. It was found quite practicable to develop 25 prints on the Tula or other gaslight paper with 10 ccs. of concentrated edinol solution. The addition of the tribasic sodium phosphate has no other effect than improving the tone of the prints, the time of development remaining practically the same. The time which a print takes to come up may be taken as a pretty good criterion of the necessity of adding the tribasic sodium phosphate. Assuming that exposure has been correct, and that the print develops up quickly, the addition of the phosphate may be omitted for the next print, but should the print come up slowly

the added quantity of phosphate solution may be increased 10 drops. It is important that pure tribasic sodium phosphate should be used, ordinary sodium hydrogen phosphate the chemists' shops being without the above specific action. Obviously, the above addition of sodium tribasic phosphate can be employed with more or less success in the case of other formulae employed for the development of gaslight papers. General directions cannot, however, be given, as the addition of three drops of the phosphate solution is sufficient in the case of some developers, whilst in others a much larger addition is necessary.

GEORG HAUBERRISER.

## Photo-Mechanical Notes.

### A Proved Formula for Zinc Enamel.

A reader of the "Photo-Engraving Notes" of the "Inland Printer" sends to Mr. S. H. Horgan, editor of that column, a formula for zinc enamel half-tone:—

After scoring these formulae one ought in decency offer something in their place, so I beg to offer one that has been working successfully for the past five years:—

Le Page's glue .....	6 oz.
Water .....	16 oz.
Bichromate of ammonia .....	240 grs.
Citrate of iron and ammonia .....	30 grs.

This solution when fresh will print in summer sunlight in 5 minutes. When aged (it never gets too old if not allowed to evaporate until too thick), in two and a half to three minutes. The older becomes the better it will be. You can't say the same of an enamel formula. "Can" glue is very good, but owing to the whitening it will often give trouble if not first diluted and allowed to settle until perfectly clear, which may take three or four weeks. Dilute with twice its bulk of water. If process glue is used, cut down exposure time from one-quarter to one-third. It is recommended to use a hardener for this formula after developing—either sunlight or a solution of chromic acid and water. Kansas sunlight is such an inexpensive article that we set the plate in the sun, where it both dries and hardens. Burn the enamel to a deep chocolate and dash into water to restore some of the temper. Remember that water is a good thing to keep away from in enamel prints, so dry your plate promptly after washing, etc. Follow these instructions, and if you were bothered with zinc-enamel troubles you will say "Thank you." Use this enamel on copper, with two ounces more water, and don't trouble to harden it unless you wish.

## Exhibitions.

### HACKNEY PHOTOGRAPHIC SOCIETY.

By an oversight, for which we have only ourselves to blame, the four days during which the Hackney Photographic Society Exhibition remained open were allowed to pass before we realised that we had failed in the duty due to this active society of reviewing the collection of pictorial work which it brings together as the result of the work of its own members, and through its appeal to photographers generally. Though the Hackney Society is almost unique in the strength of its members' classes it would none the less be unjust on that account to dismiss the show summarily as a semi-private exhibition, since it is supported by very good outside contributions. The society undertakes to collect pictures from the Royal and the Salon, and its display of the frame in the King's Hall of the Hackney Baths is very excellently done. This year the judge was Mr. A. H. Blake, who made the following awards:—

#### MEMBERS' CLASSES.

Best picture in Classes A to D: Gold medal, No. 51, Walter Self. A: Silver medal, No. 24, Wm. Rawlings; silver medal, No. 36, F. I.

Roofe; bronze medal, No. 66, W. A. I. Hensler; bronze medal, No. 84, G. H. Capper; highly commended, No. 57A, Walter Selfe; highly commended, No. 63, W. A. I. Hensler. B: Bronze plaque, No. 106, A. J. Hyder; bronze plaque, No. 144, G. H. Pearce; bronze plaque, No. 161, W. H. Witts; highly commended, No. 104, E. J. Hunt; highly commended, No. 126, E. G. Price; highly commended, No. 139, J. Cox. C: Bronze statuette, No. 165, G. B. Heath; bronze statuette, No. 223, A. Akerman; highly commended, No. 195, L. Raynor; highly commended, No. 204, F. C. Williams; highly commended, No. 220, C. J. Powell. D: Bronze medal, No. 259, A. J. Linford; bronze medal, No. 261, F. E. Roofe. E: Silver medal, W. H. Witts; bronze medal, W. A. I. Hensler; highly commended, Walter Selfe; highly commended, Wm. Rawlings.

## OPEN CLASSES.

Best picture in Classes F to H: Gold medal, No. 326, John Hepburn. F: Silver medal, No. 388, C. Wille; bronze medal, No. 271, Oscar Hardee; bronze medal, No. 395c, W. Chater Lea; highly commended, No. 288, C. A. Morgan; highly commended, No. 344, A. F. Hirschfield; highly commended, No. 348, W. A. I. Hensler. G: Bronze statuette, No. 428, Grafton Goatly; bronze statuette, No. 434, H. W. Fitch. H: Bronze medal, No. 463, Miss E. L. Marillier; bronze medal, No. 468, A. Taylor; highly commended, No. 477, G. C. Laws. I: Silver medal, W. A. I. Hensler; bronze medal, Wm. Rawlings; highly commended, E. Burton.

## FORTHCOMING EXHIBITIONS.

November 20.—Redhill and District Camera Club. Sec., J. Paterson, Ness House, Redhill.  
November 23 to 26.—Lancaster Photographic Society. Sec., J. Holt, 11, Fern Bank, Lancaster.  
December 9 to 12.—Bolton Amateur Photographic Society. Secs., A. N. H. Wylde and J. Bailey, 25, Croston Street, Bolton.  
December, 1908, to January, 1909.—Kiew International Photographic. Sec., S. T. Horovitz, Technical Society, Kreshtchatik, 10, Kiew, Russia.

1909.

January 1 to 9.—Scottish National Photographic Salon. Entries close December 7. Sec., Robert Telfer, 138, Glasgow Road, Wishaw.  
January 6 to 27.—Northern Photographic (Manchester). Entries close December 11, 1908. Sec., S. L. Coulthurst, Broad Oak Road, Worsley, Manchester.  
February 13 to March 13.—South London Photographic Society. Sec., H. Creighton Beckett, 44, Edith Road, Peckham, S.E.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for Patents have been received between November 2 and 7:—

**CAMERAS.**—No. 23,415. Improvements in photographic cameras. John Appleton and Taylor, Taylor and Hobson, Ltd., Stoughton Street Works, Leicester.

**PRINTING APPARATUS.**—No. 23,684. Improvements relating to photographic printing apparatus. William Edward Lake, 7, Southampton Buildings, London, for William Carl Huebner and George Bleistein, United States.

**PRINTING APPARATUS.**—No. 23,690. Improvements relating to photographic printing apparatus. William Edward Lake, 7, Southampton Buildings, London, for William Carl Huebner and George Bleistein, United States.

**PRINTING APPARATUS.**—No. 23,701. Improvements relating to photographic printing apparatus. William Edward Lake,

7, Southampton Buildings, London, for William Carl Huebner and George Bleistein, United States.

**PRINTING APPARATUS.**—No. 23,717. Improvements relating to photographic printing apparatus. William Edward Lake, 7, Southampton Buildings, London, for William Carl Huebner and George Bleistein, United States.

**CINEMATOGRAPHS.**—No. 23,811. New or improved means for guiding the films in cinematographic apparatus. Alfred Duskes and Duskes, Kinematographen und Film-Fabriken, G.m.b.H., 31, Bedford Street, Strand, London.

## COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

**LEVEL FOR REFLEX CAMERA.**—No. 13,536. 1908. In place of a spirit level the invention provides for the use of a small globe or globule (e.g., of mercury) which is contained in a concave glass attached to the under-side of a horizontal focussing-screen. In carrying the invention into practical effect the upper surface of such lens is slightly concave to contain a ball or globule, preferably of mercury, and has a transparent covering of glass, or where the view-finder is provided with a ground-glass focussing-screen, a slightly concave transparent glass is arranged beneath the same, allowing sufficient space between the glass and focussing-screen to contain a small ball or mercury globule. In either arrangement the ball or globule will naturally rest at the lowest point of the concavity, when the camera is level and the ball or

globe indicating the position of camera, is observed in the ordinary field of view.

Where an upper horizontal ground-glass focussing-screen is employed, as in the case of focal-plane cameras for example, a slightly concave transparent glass is arranged beneath the same and a ball or mercury globule contained between them, so as to appear in the field of view and indicate the level, while one of the glasses may be provided with cross lines or wire to indicate the central position. In the figure, *a* is the focussing-screen, *b* the concave glass, and *d* the globe of mercury or other metal. Charles Percival Truscott, 40, Glisson Road, Cambridge.

**FOLDING REFLEX CAMERA.**—No. 15,951. 1908. The invention consists of a reflex camera in which the mirror and ground-glass are hinged to the back frame of the camera, the lens-board being connected to the ground-glass frame-work by means of an intermediate member. This construction renders it possible when folding the camera to displace the lens panel from the hinge-point of the ground-glass carrier, and to move it towards this hinge-point or towards the back frame of the carrier when erecting the camera, a movement which allows of selection in the matter of focal length of lens.

The displacement of the ground-glass from the optical axis

beyond the point of rotation of the mirror preferably takes place in such manner that the ground-glass forms the cover of a bottomless box hinged to the back frame, with its bottom aperture closed and made light-proof by the mirror. In this manner a simple element of the construction prevents access of light through the ground-glass to the interior of the camera while the camera is in the working position.

In the drawing:—The lens-board is marked 2; the supporting struts, 3; the light-tight connection of lens-board to camera casing, 4; the focussing hood, 5; the ground-glass, 6; cover plates, 7 and 9; and closing flap on the latter, 10. The lens-board 2 is pivotally connected to the back frame by a wall plate 11 and ground-glass carrier 12 with hinge-pin 13, as well as by the struts 3. The adjusting mirror rotatable about the hinge-pin 13 of the ground glass carrier is marked 14. A helical spring 15 tends to move the mirror into its position of rest in which it abuts against the lower aperture of the ground-glass carrier, which forms a box-like casing open at the bottom. On the axle of the adjusting mirror 14 there is an arm 16 serving as an abutment adapted to co-act with a locking projection 17. The locking projection 17 is mounted on a resilient metal piece 18

Fig. 1.

Fig. 2.

which is fastened to the casing and can be so bent from the casing wall by a bolt 19 having an inclined plane and press button 20, that the projection 17 releases the arm 16. A spring 21 tends to hold the bolt 19 permanently in its position of rest. 22 and 23 indicate the winding rollers of a blind shutter 24, which can be held in the wound position by a pawl 26 engaging a ratchet wheel 25. The connection of the ratchet wheel 25 to the winding roller of the curtain (in the construction shown in Fig. 1 the upper winding roller) is made by toothed wheels 27, 28 of which the latter is supposed to be mounted on the axle of winding roller 22. 29 indicates an eccentric mounted on the axle of the adjusting mirror 14 and adapted to co-act with the pawl 26. 30 is a spring which tends to hold the pawl 26 in permanent engagement with the ratchet wheel 25. 31 indicates two lateral rods, with joint marked at 32, connecting the camera casing to the arms 3.

The manner of using the camera, and its action, are as follows:—

Let it be assumed the camera is in the working position shown in Fig. 1. In this case the image projected by the lens mounted in the lens board is reflected by the mirror 14 on to the ground-glass 6, and can be seen thereon through the view holes 8, so that the adjustment of the lens to the respective focus can be effected in the known manner. If after the adjustment a picture is to be taken, the adjusting mirror is released by pressure on

the button 20, and the slide 19 pushes back the resilient plate 18 carrying the projection 17 so that the arm 16 can move past the projection. As soon as the arm 16 is released the mirror 14 is rotated upwards by the action of the spring 15 so that it enters from below the box-like ground-glass carrier 12 and makes a light-proof closure of the interior of the camera. Together with the upward movement of the mirror 14 there takes place a rotation of the eccentric 29 on the mirror axle, so that at the moment at which the mirror reaches its upper position the release of the pawl 26 from the teeth of the ratchet wheel 25 is effected. A spring-pull acting in the known manner on the blind 24 then causes the shutter to act, since the toothed wheels 27, 28 no longer prevent rotation of the blind roller 22, the pawl 26 being disengaged. By winding up the blind again any desired number of pictures can be taken. When the camera is to be folded the rods 31 are bent, and the arms 3 connecting the lens board 2 with the camera casing are thus no longer prevented from rotating, and are rotated downwards; the halves of the rods 31, connected by the joint 32, are thus folded together, and the lens board is laid against the under-side of the camera casing. During this folding of the arms 31 the under-part of the bellows 4 is folded as shown in fig. 2. Together with the folding of the arms 3 with the lens board 2 there takes place a folding of the box-like ground-glass carrier 12, and of the camera wall 11 connecting the same with the lens board, these parts being moved into the position shown in fig. 2. The bellows parts 4 and 5 are laid together in the manner shown in fig. 2, and the cover 7 and folded cover 10 secure the parts from outside, so that the camera parts substantially appear as enclosed in a simple casing. By repeating the operations in the reversed order the camera can be brought back to its working condition. Optische Anstalt C. P. Goerz A. G., 44-46, Rheinstrasse, Friedenau, Berlin.

**FOLDING POCKET-CAMERAS.**—No. 17,624. 1908. This invention consists in improvements in photographic cameras of which the front and back frame are connected to one another by rigid stays. The invention relates to an improved focussing device by which the lens is adjusted from the film or plate carrier in accordance with the distance of the object to be photographed. For this purpose the joints of the stays in the camera body are arranged in bearing pieces movable in the direction of the optical axis, so that by displacement of these bearing pieces which remain permanently in the camera body the distance

between the lens and the plate carrier can be adjusted according to the distance at the time being of the object to be photographed.

The camera body is indicated by 1. In it are two lever pairs, 2 2 and 3 3, of which the first pair are connected together by a connecting piece 4, and the latter pair by a connecting piece 5, the pairs being rotatable on pivots 6 6 and 7 7. The levers of the lever pair, 2 2, extend with their contracted ends, 8 8, in recesses 9 9, of the lever pair 3 3, so that a turning movement of the one pair causes corresponding rotation of the

other pair. The reduced end of one of the levers, 2, carries a pin, 10, which projects through the wall of the box and engages in a spiral groove, 11, of the focussing disc, 12, which is seated on the outside of the box. To the lever pair 2 2 a pair of stays, 13 13, is attached by means of a spindle, 14, which rests in recesses of the lever pair, 2.

Opposite the pair of stays 13 is a pair of stays 16 which are seated on a spindle 17 which lies in a recess 18 of the lever pair 3.

Springs, 19 20, are arranged which tend to push the spindles 14 and 17 into the recesses 15 and 18. Coil springs 21 and 22 tend to hold the stays 13 and 16 in the position shown in the figure.

The stay pairs 13 and 16 engage by means of pins 23 24 in slots 25 and 26 of the back or plate-carrier 27 of the camera. 28 is a slot in the box wall in which the pin 10 extending through the wall is laterally movable, the slot being covered by the focussing disc rotatable about the pivot 29.

The action of the apparatus is as follows:—Let it be assumed that the camera is in its working position shown in the figure, and that it is desired to adjust the focus to a certain distance. For this purpose the disc 12 is rotated, causing the pin 10 to move in the groove 11 and rotate the two lower lever pairs 2 2, 3 3 about the pivots 6 6 and 7 7. This rotation of the lever pairs produces displacement of the spindles 14 and 17, since the said spindles, being permanently held by the springs 19 and 20 in abutting position in the recesses 15 and 18, must take part in all the movements of the lever pairs 2 2, 3 3. The rotation of the lever pairs 2 2, 3 3 thus produces longitudinal displacement of the stay pairs 13 and 16, and moves the plate frame 27 to or from the camera box which carries the lens, not shown in drawing. Optische Anstalt C. P. Goerz A.G., 44-46, Rheinstrasse, Friedenau, Berlin.

**FOLDING POCKET CAMERAS**, No. 550, 1908.—The invention relates to an improved pocket camera which, while provided with all the necessary attachments, is very compact and free from projecting parts and can be readily taken to pieces.

The frame of the camera is formed of two tubes, encased in wooden blocks, and metal sides, clamped together by metal plates secured on the ends of the tubes, thus forming a rectangular frame with a tube and wooden block at each end and a rectangular chamber between.

The bellows which carries the lens board is so formed that when the lens is closed down into the camera body it is turned inside out and encloses the lens. The lens when extended is supported by hinged doors or flaps which slide on their hinges into positions in which they are held open. The flaps are provided with inclined and longitudinal slots and the position of the lens is adjusted by pins working within the slots. The shutter is contained in the two tubes forming the ends of the camera and the speed of the shutter is indicated in a special manner by means of a spring finger or pointer engaged by a finger piece which adjusts the tension of the spring on the spring blind roller. The dark slide is fitted in grooves formed by bending the metal side plates or additional plates, and a hinged plate with a flanged edge prevents the dark slide from being withdrawn with the shutter. The slide is held firmly in place by means of a V-shaped spring so fitted that the end of the slide bearing on one arm of the spring presses the other on the back of the slide. Zélie Isabelle Colville, Lightwater, Bagshot, Surrey.

**KINEMATOGRAPH MECHANISM**.—No. 11,968, 1908. The invention relates to mechanism for centring the image on the screen without changing the position of the rotating disc. Arcade Mallet, 15bis, Rue Cauchy, Paris.

## New Trade Names.

**ARMOUR BRAND**.—No. 306,353. Chemical substances used in manufactures, photography, or philosophical research and anti-corrosives, but not including preparations for use in sizing and finishing paper, leather, cotton, wool, silk, and for use in sizing and finishing like goods, and not including any goods of a like kind to these excluded

goods. John E. Williams and Co., 109A, Lower Moss Lane, Manchester, manufacturers. September 22, 1908.

**ARMOUR BRAND**.—No. 306,544. Chemical substances used in manufactures, photography, or philosophical research and anti-corrosives. Griffiths Bros. and Co., 29, Macks Road, Bermondsey, London, paint, colour, and varnish manufacturers. September 30, 1908.

## Analecta.

*Extracts from our weekly and monthly contemporaries.*

### Stereoscopic Lantern Slides.

Mr. A. Lockett, writing in "The Amateur Photographer and Photographic News" of November 17 on the application of the Dixie method of stereoscopy to stereoscopic projection, described the preparation of two stereoscopic pictures on a single lantern plate, one reversed as regards right and left relatively to the other. The pictures are projected by an ordinary lantern, and to view these "the spectator should be provided with a small unframed mirror. Naturally, a surface-silvered one is best, but, contrary to what might be expected, any ordinary mirror of good quality glass can be employed without giving a noticeable double image. A common quality glass, however, is perfectly useless. The mirror is held against the nose in an upright position, pointing towards the central division between the two pictures on the screen. Then, looking at the right-hand picture with the right eye, the mirror is turned slightly until the reflection of the left-hand picture falls over the first. It is quite a simple matter, once it has been tried, to get the two halves of the stereogram to coalesce, so that one-half is seen with the left eye by reflection in the mirror, while the second half is viewed by the right eye direct. The result is that the image on the lantern screen is seen in perfect stereoscopic relief. With good subjects the effect is very beautiful, far surpassing the usual small opaque slide as inspected in the stereoscope."

### Photography for Profit.

Mrs. Marion Whitten, writing in "Photography and Focus" for November 17, on "How a Lady makes her Hobby pay its way," records her experiences. "At the end of the first six months I took a photograph of my eldest boy in his surplice. Everyone praised it, saying what a good postcard it would make. I sent it up to a big postcard firm, and by return of post I had an offer of 15s. for it. That was my grand beginning. From that time I began regularly to sell my prints of children for magazines and postcards. . . . Now after three years' work I can find a ready sale for this class of picture. . . . Thus I feel free to enjoy my love for this work with an easy conscience, although I am the mother of seven children, and could not afford to spend money in this way unless it more than paid for itself. . . . I depend on 'Photography and Focus' and the advice of one or two photographic friends to help me along, and I hope some day to do something worthy of being accepted at the Royal Photographic Society's exhibition."

**A WONDERFUL INVENTION**.—A discovery which, from the account of it in a daily paper, would appear to merit the application of the comprehensive German epithet "Ausgestaltungsfähigkeit," is said to have been made by a Professor Pierucci, of the University of Pisa. He is said to have invented "a new species of paper which is destined to revolutionise the present system of lighting, besides having numerous practical uses in electrical development owing to its remarkable conductive powers. The professor's invention is shortly to be placed on the market in a form which is intended to supersede the mantle hitherto in use in the incandescent system of lighting. The new paper will also be on sale for cartoon and photographic purposes, and for use in filtering and in bacteriological research."

## New Apparatus, &c.

The "Kinora" System of Animated Photography. Supplied by the Kinora Company, Ltd., 21, Red Lion Square, London, W.C.

The "Kinora" system of home and outdoor photography bears the same relation to the ordinary photograph as the living picture on the screen does to the lantern-slide, that is to say, in place of the one portrait of a stiffly posed sitter, it shows the sitter with his or her natural animation, the result of offering to the eye within a short space of time a series of hundreds of consecutive photographs obtained while the sitter chatted with the photographer or followed some pastime or occupation. This result is obtained, not on a screen

Fig. 1.

arranged in a darkened room, but in a roll of prints which are examined exactly in the manner of looking at an ordinary stereoscope, or may be operated in a larger instrument of the same type, by means of which a number of persons can see it at the same time. The particular project of the Kinora Company which interests us is its offer to photographers to—

(1) Supply the camera and film by which the "living portraits," groups, or incidents may be taken.

(2) Develop the negatives and supply rolls of the prints at a moderate rate.

The camera, as shown in Fig. 1, is not much larger than an

Fig. 2.

Fig. 3.

ordinary hand camera. Its mechanism provides for the use of a length of film of 42ft. and less, which is loaded into the instrument in full daylight, and is used without perforations along its edges, thus securing a larger picture. By means of a locking lever action, controlled from the back of the camera, as shown in Figs. 2 and 3, the

subject may be actually focussed on the ground glass, a single turn of the lever bringing the film mechanism into the field of the lens. The dial on the back of the camera shows the length of film used, and allows of an exposure being divided into, say, four parts as is frequently convenient when obtaining a film record of the various members of one family. The machine is stopped at any point for the change of sitters. The camera, complete with 3in. focus Ross Homocentric lens, working at  $f/4.8$ , is sold at £15 15s., or without lens £10 10s. Rolls of film, of from 12ft. to 42ft. length, are supplied at from 1s. 6d. to 5s. 3d., that is, about 1½d. per foot.

The development of the negative and the making of one record roll of prints are done at from 1s. 6d. to 4s., so that for the sum of

Fig. 4.

Fig. 5.

from 3s. to 9s. the photographer can obtain an animated record of a scene or sitter without himself doing more than make the exposures.

The record takes the form of a disc of metal, to which are attached the hundreds of prints made from the film negative. A very simple mechanism brings these one by one against the plate or stop, and thus presents the movements of the original with a high degree of realism. The results which we have ourselves seen at the office of the Kinora Company speak highly for the accuracy with which the prints are fitted to the central disc. The viewing mechanism certainly represents a reduction to simplicity beyond which it is

Fig. 6.

difficult to imagine anything further. Fig. 4 shows a simple form of table viewing instrument, costing 30s. It is operated by hand and, as we have said, resembles, in size and appearance, a substantial type of stereoscope. A more elaborate instrument is that shown in the next drawing, in which the print-roll is actuated by clockwork, the instrument being provided with two lenses, which allow of several persons looking into it at one time. In bronze metal, the Kinora costs £4 4s.

A still larger build of instrument is shown in Fig. 6, being made

to take pictures  $3 \times 2\frac{1}{2}$ , i.e., enlargement from the ordinary Kinora roll. These are supplied to take 1,000 photographs, and to run continuously by motor, and are chiefly advanced in patterns, somewhat different from that shown in the illustration—for advertising purposes in shop windows, railway stations, etc.

The chief interest in the Kinora system, as it is at present available, is the facility afforded of making and supplying records which can be used by customers in their own homes. The cost to them need not be very great, and yet the photographer should make his profit out of it—he will not have much to do beyond taking the order—obtain a good deal of local advertisement for himself, in introducing such a novel development of the art of the camera. The "Kinora" booklet, to be obtained gratis from the company, at 21, Red Lion Square, will give much information additional to what we have been able to say above as the result of our own observation.

**"Empress" Enlargers.** Made by Houghtons Ltd., 88-89, High Holborn, London, W.C.

An enlarging apparatus made by Messrs. Houghtons at their own works specially for the amateur worker is made in a variety of patterns, among which the "Empress," now before us, is marketed complete at the low price of £2 12s. 6d., in the quarter-plate size. For this sum the purchaser obtains the apparatus, with 5½ in. condensers, projection lens, and orange cap. The lantern body is of form suitable for incandescent gas burner, the outfit for which (tray, jet, burner, and reflector) is sold at an extra cost of 7s. 9d., but any

other light of moderate power, such as lime, acetylene, or oil, may be used. The enlarger is most strongly made, is fitted with sliding negative carrier, and is certainly very good value for the moderate price charged for it. Messrs. Houghtons' full list of enlarging lanterns and accessories may be recommended for reference by those investing in an outfit. It is sent free.

**The Klito Daylight Lantern Slide Reducing Camera.** Made by Houghtons, Ltd., 88-89, High Holborn, London, W.C.

This new model of the very convenient fixed focus reducing camera possesses the useful feature that the portion carrying the plate is "rotatably attached," as the patent specifications say, to the front, with the result that the line of, say, a house or telegraph post, which in the negative is not parallel with the side of the plate as it should be, can have its divergence from vertical rectitude amended in the

lantern slide. This facility does not in any way increase the size of the appliance, which, in the case of the reducer for quarter-plate negatives, is  $4\frac{1}{2} \times 4\frac{1}{2} \times 13$  inches. The camera is well made in wood throughout, leather-covered and fitted with lens, shutter, and dark slide. We have ourselves tested its correctness of adjustment. It

is obtainable to reduce to  $3\frac{1}{2} \times 3\frac{1}{2}$  from quarter,  $5 \times 4$  or half-plate negatives, at the respective prices of 12s. 6d., 13s. 6d., and 15s.

**THE "MASCOT" DRYING LINE.**—For the drying of film negatives and prints Messrs Houghtons Ltd. are supplying a strip of stout holland, complete with a dozen clips, the modest outfit being a useful

device, such as is constantly of service when a few prints or film negatives have to be dried. Boxed in the customary attractive style of the Houghton firm, it is sold at 1s.

**THE MORTIMER PIGMENTING TRAY.**—Under this name, Messrs. John J. Griffin and Sons, Ltd., have placed on the market an accessory for the use of workers in the "oil" and "bromoil" processes. The essential part of the apparatus is the compartment in the tray, which can be filled with sheets of wet blotting-paper, over which

a piece of fine linen supported on a metal frame can be laid. The oil print laid in turn on this latter is thus kept in a moist state during the pigmenting process, without, however, acquiring odd fragments of blotting paper. The tray allows of this useful dodge being put most conveniently into practice, and is sold by Messrs. Griffin of a size to accommodate prints up to  $15 \times 12$  in.

## New Materials, &c.

**The "Barnet" Studio Extra-Rapid Plate.** Made by Elliott and Sons, Ltd., Barnet, Herts.

Recent trials of some of the plates now being issued by Messrs. Elliott specially for the professional photographer under this name have enabled us to confirm the claim of the makers for a plate of high speed, and at the same time of great cleanness of working. The "Studio Extra-Rapid" certainly does not belie its name, and we were fully satisfied with its behaviour in development and the brilliancy and quality of the negatives obtained by giving exposures for a plate of high rapidity. Messrs. Elliott, it should be said, have the professional photographer primarily in view in introducing the plate, and are therefore making the special offer to send a parcel of three dozen half-plates for the purpose of a preliminary trial on the receipt of 5s. Those who avail themselves of this offer may at the same time inform themselves of the liberal terms upon which Messrs. Elliott will undertake to supply regularly.

**Black "Japine" Platinotype Paper.** Made by the Platinotype Company, 22, Bloomsbury Street, London, W.C.

The Platinotype Company have just placed on the market a new variety of the platinum paper introduced by them under the name of "Japine" some two years ago. "Japine" platinotype, it is

scarcely necessary to recall, constituted an advance in platinum papers in the direction of surface. Its predecessors had all marked characteristics in the degree of roughness or distinctiveness of texture—which varieties are still highly appreciated for various effects—but the “finest” surface has still a matt, and therefore the “Japine” platinotype, with its “semi-matt” surface, with enough sheen to prove particularly valuable in the shadow portions of the print, was naturally welcomed, particularly by professional photographers, for whose purposes a print with a surface not matt yet not glossy is eminently desirable. That “Japine” gave a print of sepia colour was not regarded as a drawback to it, but the full range of choice among the manufactures of the Platinotype Company has now been completed by the present introduction of a “Japine” which has the surface of “Japine No. 1,” but yields prints of the pure black colour which has always been the distinguishing mark of the platinum printing process.

Black “Japine” is used in precisely the same way as its sepia prototype, or, in fact, like cold bath platinum. The standard half-strength developer is prepared by dissolving the Platinotype Company's salts in 48 oz. of water and diluting with an equal quantity of water to form the developer, in which the “Japine” print obtains its full vigour in less than a minute. The print is then treated in two acid baths and washed as usual. The dry paper, both before exposure and after development, requires to be handled with somewhat more care than the ordinary brand, owing to the different nature of its surface, but beyond this precaution the mechanical treatment of the prints calls for no special remark.

It is no trite excuse for an inadequate vocabulary to say that the results upon the new paper must be seen, not only described, to be appreciated. Adjectives, however exactly used, fail to convey the precise qualities which characterise a photographic print, but special emphasis may be laid upon the brilliance of, and detail in, the highlights of the “Japine” print, and the tonal variations of the shadows—both in the same print. The maximum range of gradation has long been conceded to the platinotype print, but the “Japine” paper would seem to excel the ordinary brands in this respect. Another characteristic is the rich pure black of the print, which thus obtains a decisiveness which, in some manner difficult to analyse, sets a stamp of quality upon the print. And as that is a consummation devoutly to be wished by photographers—who are quick to see that such a quality should go hand in hand with a handsome price—there are obvious reasons other than æsthetic ones for printing in “black Japine.” Indeed, it is scarcely too much to say that if the future historian of photography, judging by the prints of the present era which descend to him, be called upon to say what form of photograph he would describe as the triumph of photographic printing, he will point to an example of “Japine” platinotype. If the present proprietary and staff of the Platinotype Company can never hear such encomiums of posterity they will surely be consoled by the present approval (of the photographers best able to judge) of their persistent determination to produce, as they have done in the present instance, only the best of which they are capable; and they surely cannot expect higher praise than this.

WELLINGTON CHRISTMAS GREETING POSTCARDS.—Messrs. Wellington and Ward send us specimens of the greeting postcards issued by them for the approaching season, in a series of six different designs, embodying appropriate mottoes. The cards are marketed in all the well-known Wellington brands of papers, and in the two regulation sizes of  $5\frac{1}{2} \times 3\frac{1}{2}$ , and  $4\frac{1}{2} \times 3\frac{1}{2}$ . The prices are as follows:—

REGULATION SIZE:  $5\frac{1}{2} \times 3\frac{1}{2}$ .

Bromide: Matt, glossy, and carbon, in packets of 18 cards, for 1s.; and in packets of 8 cards for 6d.

S.C.P.: Matt, glossy, and carbon, in packets of 18 cards, for 1s.; and in packets of 8 cards for 6d.

P.O.P.: Matt, glossy, and carbon, in packets of 12 cards for 6d.

Self-Toning: Matt and glossy, in packets of 12 cards, for 1s.

COURT SIZE:  $4\frac{1}{2} \times 3\frac{1}{2}$ .

Bromide: Matt, glossy, and carbon, in packets of 12 cards, for 8d.

S.C.P.: Matt, glossy, and carbon, in packets of 12 cards, for 8d.

P.O.P.: Matt, glossy, and carbon, in packets of 16 cards, for 6d.

Self-Toning: Matt and glossy, in packets of 12 cards, for 8d.

The designs are supplied in packets assorted, or in grosses or thousands from assorted designs to order.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

FRIDAY, NOVEMBER 20.

West London Photographic Society. “On the Printing, Developing, and Toning of Velox Papers.” W. F. Slater.  
Mill Camera Club. “Photographic Tiles.” W. Mansfield.  
Sutton Photographic Club. “Autotype Co.'s Carbon Process.” J. Braham.

SATURDAY, NOVEMBER 21.

Aberdeen Photographic Art Club. “Bird Photography.” Thomas Tait.

MONDAY, NOVEMBER 23.

Scarborough and District Photographic Society. “Elementary Enlarging.” B. A. Kenny.  
Bletchingley and Nutfield Camera Club. “On the Printing, Developing, and Toning of Velox Papers.” W. F. Slater.  
Bradford Photographic Society. “Nature Poets and Nature Pictures.” Per Lund.  
Kidderminster and District Photographic Society. “Hints and Tips.” A. Gordon Smith.  
Stafford Photographic Society. “Enlarging.” A. L. Yapp.  
Southampton Camera Club. “On the Fringe of the Austrian Alps.” C. Howdill.  
Cripplegate Photographic Society. “Plates and Development for the Printing Process to be Used.” C. W. Coe.  
Graysend Photographic Society. “The Humble Beauties of the Flower World.” E. Seymour.  
South London Photographic Society. “Enlarging.” E. W. Taylor.

TUESDAY, NOVEMBER 24.

Royal Photographic Society. “Wild Birds and their Ways.” W. Bickerton.  
Chelmsford Photographic Society. “On the Printing, Developing, and Toning of Velox Papers.” W. F. Slater.  
Nelson Photographic Society. Exhibition of Thornton-Pickard Prize Slides and Apparatus. R. Hesketh.  
Hanley Photographic Society, Y.M.C.A. “Dordrecht and District.” E. Markham.  
Hackney Photographic Society. “Lantern Slides of President's Outing.”  
Leeds Photographic Society. “The Dead Cities of the Zuyder Zee.” Thomas Green.  
Birmingham Photographic Society. “Canals, Carillons, and Coifs.” C. Howdill.  
Kinning Park Camera Club, Govan. “Yesterday and To-day.” Furrough Wellcome & Co.

WEDNESDAY, NOVEMBER 25.

L.C.C. School of Photo-Engraving, Bolt Court. “Beauty and Sincerity in Art.” W. Seymour.  
Borough Polytechnic Photographic Society. “Afar in the Fatherland.” W. L. Wastell, F.R.P.S.  
Croydon Camera Club. “The Photography of Coloured Objects.” C. E. Kennel, D.Sc.  
South Suburban Photographic Society. “Some Models I Have Photographed.” F. R. Salmon, F.R.P.S.  
Rochdale Amateur Photographic Society. Exhibition of Thornton-Pickard Prize Slides and Apparatus. R. Hesketh.  
East Kent Scientific Society. “On the Printing, Developing, and Toning of Velox Papers.” W. F. Slater.  
North Middlesex Photographic Society. “The Humble Beauties of the Flower World.” E. Seymour.  
Leeds Camera Club. “Preparing the Exhibition Print.” T. Lee Syms, F.R.P.S.  
Wimbledon Park Photographic Society. “Lantern Slides and How to Make Them.” E. Prior.  
Edinburgh Photographic Society. “The Improvement of the Negative.” Andrew H. Baird, F.R.P.S.

THURSDAY, NOVEMBER 26.

Handsworth Photographic Society. “Flashlight Photography.” R. H. Phillips.  
Trent Camera Club, Stoke-on-Trent. “Dutch Lantern Pictures.” A. E. Stubbins & Co.  
Liverpool Amateur Photographic Association. “Rambles and Scrambles on Pacific Slope and in the Yellowstone Regions of the Far West.” Harold Young.  
Chelsea and District Photographic Society. “Lantern Slides by Reduction.” A. S. Long.  
Rugby Photographic Society. “The ‘A.P.’ 1908 Prize Slides.”  
Richmond Camera Club. “Tynedale with Reference to Old Roman Wall.” H. Dale.  
Batley and District Photographic Society. Exhibition of Thornton-Pickard Prize Slides and Apparatus. R. Hesketh.  
North-West London Photographic Society. “A Dive into Belgium.” W. L. Wastell, F.R.P.S.  
London and Provincial Photographic Association. “The Christian Monument at Rome.” S. J. Beckett.  
Maidstone and Institute Camera Club. “Flower Photography.” E. Seymour.  
L.C.C. School of Photo-Engraving, Bolt Court. “Some Considerations Affecting Photo-Mechanical Etching.” A. J. Newton.  
Melbourne (London) Camera Club. “On the Printing, Developing, and Toning of Velox Papers.” W. F. Slater.

### ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held November 17. The President, Mr. J. C. S. Mummery, in the chair. The eleventh Traill-Taylor Lecture was delivered by Dr. E. Wandersleb, of the Carl Zeiss Scientific Staff, Jena, on subject of “The Regulation of the Rays in a Lens-system.” Wandersleb read his lecture in excellent English, and, as anticipated in our announcement of the discourse treated his audience to a clear and masterly exposition of the most modern way

considering what in England we generally style the "action of a lens." After briefly touching upon pure geometrical optics and the limitations of the Gauss theory, he went very fully into the theory of pupils introduced by Professor Abbe, the theory of the plane focussed for, or "objective plane" as it is sometimes called, due to Dr. von Rohr; and finally completed the exposition by an account of the effect of pupils and "lukes" combined. Unfortunately, the science of optics is so much behind-hand in this country that some students have not even reached a knowledge of the Gauss theory of principal planes. Few excepting among professional opticians have any full knowledge of the Abbe theory of pupils, while we believe Dr. Wandersleb is the first to explain in English the important effects of the "luke." Those who have studied the pupil theory are, of course, aware that the pupils of a lens are images of the stop aperture formed by the front and back combinations of a doublet objective. Similarly the "lukes" are the images of the margins of the respective combinations. While the entrance pupil bounds the amount of light that passes through the diaphragm aperture, the entrance "luke" bounds the principal rays that pass through the centre of the diaphragm. Therefore, by considering the pupils and the "lukes" together, allowance is made for the cutting-off effects of the lens mount, etc. Of course, in these modern theories of a lens' action the assumption is made that the lens is free from aberration. The older Gauss theory was, of course, incomplete, as in the case of actual instruments it only applied correctly to light-pencils of very small obliquity. The newer theories go farther than this and permit a far more general and complete view to be taken of the full action of the lens. We look upon this lecture as a most important one of the Traill-Taylor series, as no such complete summary of the most modern German theories has hitherto been presented in this country.

On the proposition of Dr. C. E. Mees, seconded by Mr. George E. Brown, a vote of thanks was passed to Dr. Wandersleb, to whom the medal commemorating the lecture was presented. Dr. Wandersleb's brief acknowledgments brought the meeting to a close.

#### THE PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

A meeting of the General Committee was held at the Royal Photographic Society, 66, Russell Square, W.C., on Friday, November 13. Present: Messrs. F. A. Bridge, Alfred Ellis, E. C. Elliott, S. H. Fry, H. E. Hull, L. Langfrier, A. Mackie (hon. sec.), D. Procter, Lang Sims (hon. treasurer), C. H. Skillman, and Fellows Willson. In the absence of the president, Mr. A. Ellis took the chair. The hon. secretary read names of five new members who had joined during the month.

The hon. secretary reported that the case of the "Throne" disrupting the charge made by a member for reproduction fees had resulted in a County Court summons being issued, and the amount had been paid into court.

The case of the prosecution of a free enlargement canvasser by Mr. Thorneycroft, of Wolverton (reported in the "B.J." of October 16), was discussed. The decision of the magistrate was considered an extraordinary one under the circumstances, and the hon. secretary was instructed to write to Mr. Thorneycroft on the subject.

A discussion followed on the possibility of coming to an arrangement with the Press with regard to the use of photographs for which permission had not been previously obtained from the photographer.

Mr. E. C. Elliott, in opening the subject, said that during the last two years he had had some conversation on the general question of copyright and the relation of photographers with the Press with influential members of that body, and they had taken a good deal of interest in the matter, and pointed out the defects in copyright matters. They unanimously expressed the desire that some arrangement should be come to by which photographers could be approached on the matter, and this resulted in the secretary of the Newspaper Society, who is also secretary to the Press Association, calling upon him, at the request of the committee of the society, to talk the matter over informally and go into the question whether some better understanding could not be arrived at with regard to the dealings of the Press with photographers, and especially with regard to the question of payment for unauthorised reproductions. The secretary pointed out that the necessity frequently arose of publishing a photograph of a person who, for some reason or other, became suddenly notori-

ous, and there was not always time to obtain permission of the holder of the copyright. As a result trouble frequently arose between the newspaper and owner of copyright as to terms, and he, Mr. Elliott, thought, with the secretary of the society, that it would really be to the advantage of photographers if some satisfactory basis could be arrived at in such circumstances. Mr. Elliott informed the secretary that he was of opinion that the whole question was one that should be dealt with by the P.P.A., which had done an immense amount of work in settling copyright claims, arbitrating unjust claims, etc., and he therefore suggested that the matter be referred to the Association, who would, he felt assured, go thoroughly into it. The Newspaper Society were quite prepared to depute a sub-committee to meet another of the P.P.A. on the subject. Mr. Elliott said he knew for a fact that for some years past newspapers have been in very close conference, and knew what their rights were, and that there was a very strong feeling amongst them that they have not always been treated well, and he thought that every effort should be made to come to a proper working understanding. He himself felt that the Association should consider this matter. He had little doubt that the two associations could come to an agreement and could formulate some scheme from which a very great deal of good would arise. The newspapers realised they could not very well do without photographers, and every day the use they made of photographs was increasing. It was true that neither the Newspaper Society nor the P.P.A. could bind directly in any way those outside their membership, but such an agreement as was proposed might in time establish a trade custom which would have the force of a law.

After discussion by the members Mr. Ellis said it seemed to him that there was a good opening here for doing a good piece of work, and he thought it would be better if the General Committee were willing to leave the matter for a time with the Copyright Sub-Committee. He also suggested that the sub-committee should be allowed to communicate with any other photographers who were not members, in order that they might get an opinion from the bulk of photographers. This might also be the means of strengthening the society, and could not do any harm. This resolution was put to the meeting and carried. Several other cases were considered, which it is inadvisable to refer to publicly.

**CROYDON CAMERA CLUB.**—Mr. T. K. Grant talked on Autochromes last week, his remarks being illustrated with a series of magnificent slides. Their size (18 by 13 cm.) necessitated the club's enlarging-lantern being requisitioned, a white-flame arc, kindly lent by Dr. Mees, giving probably the best rendering of colours possible with artificial illumination. Mr. S. H. Wratten manipulated the improvised projection apparatus. Lovely, indeed, were most of the Autochromes shown on the screen, and whether Art or not—spelling "Art" with a great big "A"—the most up-to-date impressionist could hardly deny that the process is capable of producing pictures of the utmost beauty and realism, although it only strives to reproduce "Nature" with fidelity, shade by shade, and colour by colour.

The lecturer opened with a particularly happy exposition of underlying principles. His hearers were asked to consider the coating of the plate to consist of collective groups of three starch-grains, each dyed with one of the three primaries. Light passing equally through the three was equivalent to "white." Cover up any grain and the colour would be "white," minus the colour blocked out. For instance, if the blue grain were hidden, the remaining red and green grains gave the complementary colour—"yellow." For estimating exposures, he used a Wynne meter, reckoning the plate speed as follows: On a bright sunny day Wynne  $f/14$ ; diffused daylight, Wynne  $f/11$ . In dull light, Wynne  $f/8$  would be about right. In a well-lit interior, if an exposure were given equal to the actinometer time, then a result would be obtained which (following the latest instructions for modifying development) should be satisfactory. The special green safe-lights now allowed the progress of development to be watched. In all cases it was assumed that a stop not smaller than  $f/16$  be employed. If any error in exposure were made, that error should invariably be on the side of over- rather than under-exposure; the percentage of failures would then be considerably reduced. Various complaints as to the permanganate reducer getting out of order had reached him, doubtless due to improper methods of making up this solution. The method used at Lyons, and adopted

by himself, was to keep the permanganate and acid in separate bottles, mixing immediately before use. The plate when immersed looks at first muddy, then brightens, and finally clears. Visual inspection was best here. The redeveloper should be freshly prepared, and the plate redeveloped in excess, if anything, of the time given in the instructions. Questions as to the amount of light which should be allowed to reach the plate when being redeveloped had been dismissed. From experiments made, no difference was discernible between one half of a plate redeveloped in direct sunshine, and the other half manipulated in diffused daylight. The fear of solarisation would therefore appear to be very remote.

Turning to intensification, the lecturer said no plate could be considered complete without it; in fact, no plate can be held to be correctly exposed which does not require after-intensification. This did not necessarily mean increased density. With a plate correctly treated 40 seconds at 60 Fahr. should be sufficient; the solution first turns brown. At the first sign of this colour turning to a brown-black it should be discarded. If intensification be incomplete the plate should be given a short wash, a rinse in the oxidising solution, another short wash, and reintensified. A fungoid growth sometimes occurred in solution F. The following modification of the formula was effectual as a preventive:—Water, 900 ccs.; citric acid, 3 gms.; pyrogallie acid, 3 gms.; salicylic acid (half per cent. solution), 100 ccs.

Defects which might occasionally occur in the finished Autochromes were little green and black spots; he had pleasure in suggesting for the first time remedies for both. Green spots might be due to too strong a spring in the dark-slide, or to dust. They were readily removed with a needle, the tiny cavity, after varnishing, being filled up with water-colour pigment. The same course of treatment might be adopted with black spots, or better, they could be removed by the "Wellington" bromide reducer, but about three times the strength given in the "British Journal Almanac." (The thiocarbamide reducer given on page 883 of the forthcoming 1909 "Almanac" is presumably here meant.—Eds. "B.J.") This should be carefully applied to the spots, followed by immersion in the fixing-bath and subsequent wash. The lecturer laid stress on the necessity of varnishing in every case; the varnish was poured on cold, any excess being allowed to drain off, inside the sleeve being an inconvenient but usual receptacle before the "knack" was acquired. Cementing with balsam was even more interesting than varnishing; he had been engaged in the pleasing occupation that day, and the last stage of his wearing apparel was such that no offer from any second-hand dealer in garments could reasonably be expected. For lantern work Canada balsam afforded a greater protection than varnish, though the latter was sufficient. Some discussion had taken place in the past as to whether Messrs. Lumière had discarded the original black "filling," relying upon the increased area of the grains when crushed to fill up the interstices. The correct solution appeared to be that both methods were still in force to prevent light passing other than through the coloured granules.

An animated discussion, relevant and irrelevant, followed the lecture. In answer to a question as to the keeping properties of Autochrome plates, Mr. Grant said that only the other day he had used plates from batch 86, made at the end of August last year; excellent results were obtained. After exposure, plates had also been kept by him for six months, and then developed without any apparent loss. Damp was the greatest enemy, but if stored with ordinary care they should remain in good condition for six months at least. Other speakers confirmed the lecturer's observations, and it was pointed out that although Messrs. Lumière placed a date limit on the boxes, yet that did not necessarily imply that the plates would be unserviceable subsequent to such date. A query was also raised as to the permanency of the dyes used to impregnate the starch grains, and a case was instanced in reply when an Autochrome, since June last year, had been continuously exposed in a window to all the sun Glasgow could boast of. No perceptible change had taken place.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—Meeting held November 12, Mr. Furley Lewis in the chair. Mr. P. R. Salmon lectured upon "Models I Have Photographed." His remarks took the form of hints to would-be workers doing portraiture at home. A series of fine slides were shown, showing the effects of different lighting arrangements, the use of light and dark backgrounds, etc. Some forty-five portraits of the same sittings, all taken in the same

room, but with slightly different lighting and different focus lenses showed what could be done at home in an ordinary room. The slides exhibited a vast difference of expression, and the lecturer stated that all the results were obtained by the aid of the shutter, the lighting, and the varying focus of the lens. Speaking of the tones of some of the slides shown, he said that they were all done upon Ilford "Alpha" plates, some were intensified with mercury and ammonia, but he was surprised that, when so treated, they gave a beautiful warm brown image instead of the black which he expected.

## Commercial & Legal Intelligence.

A BRITTON BANKRUPTCY.—How an amateur photographer tried to carry on a high-class photographer's business without much knowledge of the art and with practically no capital was related in the London Bankruptcy Court before Mr. Registrar Brougham on November 13, when Walter William Powell, of 4, Barrington Road, Brixton, and formerly of 414, Brixton Road, photographer, appeared for his public examination. The liabilities expected to rank for dividend are put at £354 13s. 6d., and the assets are a number of book debts estimated at £12 9s. 8d. In his examination by the Official Receiver (Mr. Grey) debtor said that in March, 1897, he commenced business as a photographer, having an amateur's knowledge. He had practically no capital, and borrowed £50, and with this, and what he otherwise possessed, bought the stock of the photographer's business at 414, Brixton Road for £80. At the end of the first year he had exhausted all his capital, and from then, he agreed he had been going from bad to worse. He was, however, always able to make good the losses. Subsequently he tried to turn the concern into a high-class photographer's business, and he engaged a staff of assistants, to whom he paid £6 18s. a week in wages. In 1900 the business reached its high-water mark, his takings for the first three years fluctuating between £500 and £700 a year. From then business rapidly declined owing to shortness of money. Debtor said that to make a living out of the business he would have to take at least £1,000 a year. In 1905 his creditors began to press him and in December of that year he made a payment for rent to clear it up to July of that year. The business was eventually closed in August, 1907, the landlord taking possession of the premises. There was an amount then owing for rent of over £300, the yearly rent being £100, and £78 a year for the use of the plant. He estimated that the value of the goods that were left in the premises when they were closed amounted to £89. Replying to further questions, debtor said that in February, 1905, he realised that he could not pay his debts out of his assets, but he continued the business in the hope that it would improve. Some of his friends had now promised to start him in business again if he could get his debts cleared through that Court. Insolvency was attributed to heavy expenses and bad trade. The examination was concluded.

### NEW COMPANIES.

ANIMATED PICTORIAL ENTERPRISES, LTD.—Capital, £10,000, in £1 shares. To carry on the business of music-hall, opera-house, cinema, photograph, or café chantant proprietors, caterers for public entertainment, etc. The subscribers are: W. Firth, Craven Bank Chambers, Bradford; W. F. Jury, 142, Long Acre, W.C., animated picture dealer, and A. Moul, 53a, Shaftesbury Avenue, W.C. Private company. The first directors are: W. Firth, W. F. Jury, and A. Moul (all permanent). Qualification, £100. Remuneration as fixed by the company.

AD. PHOTO. COMPANY, LTD.—Capital, £300, in £1 shares. To supply business houses, tradesmen, and others, with display frames containing news, photographs, or pictures of topical and other events as a window attraction, to supply fresh photographs from time to time to incorporate into such frames local or other advertisements for display, etc. The subscribers are: J. G. Sparkhall, 10, Martell Road, W. Dulwich, S.E. and F. de P. Romani, 36-8, Whitefriars Street, E.C. Private company. The number of directors is not to be less than two or more than seven. The first are to be appointed by the subscribers. Qualification, £25. Registered office: 36-8, Whitefriars Street, E.C.

## News and Notes.

**"TRANSIENT PHOTOGRAPHERS."**—We read in the "Bulletin of Photography" that the studio proprietors of Des Moines, Iowa, who, like other photographers in the States, have been troubled with the travelling canvassing person, have circulated a petition among themselves to be presented to the City Council, in the future asking that body to pass an ordinance putting all transient photographers under licence. This is the result of a scheme several outside men have worked who have blown into the city and made a house to house canvass selling coupons, thus collecting a large sum of money and then suddenly leaving. The local men claim that it has destroyed the confidence of the people in those engaged in a legitimate business and caused them to lose a great deal of their trade, so in order to protect themselves they will ask the City Council to place any soliciting photographer under strict regulation.

The following is the petition that will be presented, signed by all of the men who are operating studios:

"Honourable Mayor and City Council:

"We, photographers of Des Moines, request your honourable body to pass an ordinance regulating the work of transient photographers in this city.

"We believe that non-residents who come here, selling their wares from house to house and entering into direct competition with us, should be obliged to pay a licence fee, and should otherwise be governed by the city.

"A measure such as we desire will not only benefit us, but will serve as a protection to many people who spend big sums of money for cheap work, and as a protection to persons who are frequently drawn into picture fakes. As the superintendent of the Department of Public Safety probably knows, picture-fakers are numerous, and we feel that for all the reasons stated we are entitled to a measure of relief."

**INTENSIFIED LIMELIGHT.**—"I venture" (writes Mr. C. E. S. Phillips, to "Nature"). "to direct your attention to a simple device which I have found very useful for increasing the light from a demonstrating lantern. It is usual, on account of their long life, to use so-called artificial lime cylinders, even though they give somewhat less light than pure lime ones. An ordinary Welsbach gas-mantle happens to fit all these cylinders, and should be slipped on before the jet is lighted. The increase in brightness of the light due to this addition is astonishing. The mantle is only slightly damaged by the jet, and by turning occasionally so that the flame impinges upon a fresh place, the intense illumination may be maintained for two hours or so."

**AMERICAN RIGHTS IN PORTRAITS.**—The Court of Appeals at Albany, N.Y., on October 23, declared constitutional a law passed in 1903, which declares that the picture of a person cannot be used for advertising or trade purposes without his consent. In 1903 Chief Justice Alton B. Parker, of the Court of Appeals, in decision, determined that a right of privacy enforceable in equity did not exist in this State such as would enable a woman to prevent the use of her portrait for advertising purposes without her consent, but he pointed out that the Legislature could enact a law to ensure such privacy. This the Legislature promptly did. Under this law Aida T. Rhodes (according to the "Bulletin of Photography") sued the Sperry and Hutchinson Co. for displaying her picture in its Manhattan office among its premium exhibits, which were exchanged for trading stamps. She secured a decision in her favour, prohibiting the further use of her photograph and a verdict giving her \$1,000 damages. The Brooklyn Appellate Division affirmed the trial term decision, and so did the Court of Appeals. The company fought the constitutionality of the law, which is upheld by the Court of Appeals in an opinion written by Justice Willard Bartlett.

In discussing the operation of the law, Justice Bartlett says:

"The new law is wholly prospective in its operation and hence does not apply to previously acquired pictures. Upon portraits the ownership of which was in others at the time when the act took

effect its provisions are inoperative. Such pictures the owner is still at liberty to use for advertising or trade purposes, without being held thereby to have been guilty of a crime or to have committed a tort. His property rights therein are unaffected by the statute.

"On the other hand, as to pictures whose ownership remained in the person represented at the time when the act took effect or portraits subsequently made, a transfer of ownership no longer carries with it the right to use the picture for advertising purposes unless the written consent of the person portrayed shall have been given. The acquisition of such picture by itself does not carry with it the right to use it for advertising or trade purposes except with the written consent of the person represented."

**A FORTHCOMING WORK.**—Mr. Henry Frowd is about to publish "Fonts and Font-Covers," by Mr. Francis Bond, a companion volume to that author's "Screens and Galleries in English Churches." The last general account of fonts given was that by Mr. Paley in his introduction to the collection of 123 fonts made by Mr. T. Combe in 1844, and there exists no consecutive account of the very beautiful font covers which survive of Gothic and Renaissance design. Mr. Bond treats his subject historically, showing side by side the gradual modifications of doctrine and ritual which obtained in the mode of administration of the rite of baptism. There are upwards of 400 illustrations showing fonts and font covers of all periods.

**A PHOTOGRAPHER'S SUICIDE.**—The Croydon Coroner held an inquest last week on the body of Frederick James Robinson, 53, a photographer. The deceased had suffered from depression and sleeplessness for about a year on account of bad business. He often complained of headaches. Deceased had all the symptoms of prussic acid poisoning, and the medical man found a bottle which contained a solution of cyanide of potassium. Death was due to prussic acid poisoning. The jury returned a verdict of suicide during temporary insanity.

**PIGEON PHOTOGRAPHERS.**—According to the "Daily Mirror," taking photographs during flight is the latest use to which carrier pigeons have been put by Dr. Jules Neubronner, of Falkenstein, Germany, who has devised a tiny photographic chamber which will take distinct photographs during the average speed of flight of twenty yards per second. The photographs are taken on films, 1 in. square, of which there are thirty; while a shutter opens automatically every thirty seconds by means of a small india-rubber bulb pressed by clockwork. Trials show that a pigeon can carry the apparatus, weighing 2½ oz., for ninety miles without fatigue.

## Correspondence.

\* \* Correspondents should never write on both sides of the paper.

No notice is taken of communications unless the names and addresses of the writers are given.

\* \* We do not undertake responsibility for the opinions expressed by our correspondents.

### A SOCIETY FOR NIGHT PHOTOGRAPHY.

To the Editors.

Gentlemen,—In various societies in town and country I have met members who, like myself, are keenly interested in night photography. By night photography I do not mean "fakes" or results obtained by combinations of daylight and night exposures, but results obtained solely after dark by natural and ordinary artificial light. This is, I am persuaded, a new field for pictorial effect, but little explored and little used, and those who are trying to find out more about its conditions and extend its scope would gain much by co-operation with those engaged in a similar quest. If those who are interested in this matter will communicate, in the first instance, with me I will take upon myself, until some sort of organisation is formed, to call together those who write that they have had some experience of this kind of work, and who may wish to join either a Portfolio

Club or a society.—Thanking you in advance for the hospitality of your columns, I am, gentlemen, yours very truly,  
A. H. BLAKE.  
Blenheim Club, King Street, St. James's,  
November 17, 1908.

#### NEWSPAPER HALF-TONES.

To the Editors.

Gentlemen,—We think you would be interested to know some thing about Patent Application No. 21752. The enclosed proof was printed from a wood block, engraved directly from a hardened plaster mould of a wet carbon print, the whole operation taking about one hour. As the patent is only in its application state, we cannot now describe the machine fully, except to say that the block can be cut any depth, regardless of the depth of the relief. Any

relief can, of course, be used, and for speed those formed by the tanning action of developers or bichromates on dry-plates would be suitable.

Owing to the depth and shape of cut, we think the process will be excellent for stereotyping and rough paper printing.—We are, yours truly,  
A. E. AND W. H. SAY.

2, Whitefriars Street, E.C.  
November 13, 1908.

#### RETOUCHERS' CRAMP.

To the Editors.

Gentlemen,—It is commonly stated that letter writing is a lost art, which may account for the fact that we seldom hear nowadays of what is commonly called "writers' cramp." This, however, is not a lost complaint. Authors and other scribblers can escape it by resorting to the typewriter, but what about the poor retoucher? The golden age when retouching shall no longer be required, and when that dead art will appear like the recollection of an ugly dream, has not yet arrived; in the meantime a few privileged workers have acquired the disease by years of patient toil and incessant use of the pencil. I am induced to write about the matter by reading a letter in a recent issue of the "B.J." of a fellow-worker who complains of trouble with his thumb. I may preface my remarks by stating that I have been retouching incessantly for over thirty-five years, and that therefore it is not to be wondered at that fate, in the shape of "retouchers' cramp," has overtaken me.

It is now quite twenty years ago, that one day, sitting at work, joyous and contented, for of work there was plenty and the weather beautiful, all of a sudden the forefinger of my right hand darted up erect, stood for a few moments, and dropped on the pencil again. I laughed, and the playful beggar, obliged again, and once more. About a week after, it began again, then a few days after, then every day, and then always accompanied by a cramp, which made work very unpleasant. I then, by the advice of various friends, resorted to all kinds of expedients, as tying the pencil to the finger, or the finger to its neighbour, using heavy dumb-bells and swinging an iron head-rest around my head, soaking the hand in oily rags

at bedtime, and submitting to fish diet. But of no avail. I then underwent a select course of agony for about two years, and last, what I should have done at first, consulted a specialist. After about two months' wrestle with electricity, massage, and injection of strychnine in the arm, I was cured, so much so that during the years immediately afterwards I was able successfully to do the most severe and incessant work any retoucher ever did. Alas! About two years ago the hand got worse again, and at last refused service altogether. I had then perforce to take to my left, and by dint of patience and perseverance succeeded in gaining the necessary mastery of that hand. I had read in a medical book, when I had my first attack, that using the left was no good, as it would soon follow suit. It did! After I had used it for a year one fine day I momentarily lost power over the pencil; but, strange to say, this time it was not the finger that was attacked, but the arm. After I had worried over that for some time, hoping it would pass away, I again consulted a specialist, and he diagnosed my complaint as Penman's Palsy. So that at the present time I am the happy possessor of writer's cramp in the right hand and Penman's Palsy in the left arm, both of which possessions I should be glad to pass on to anyone who would like them. This time the treatment is again electricity, and a tonic containing strychnine, and I am happy to say I am able to work, though slowly and somewhat painfully. But the best treatment and a sure cure, the kind doctors advise me, is complete rest for twelve months, say, a nice trip round the world, or to bask in the sunshine of a genial clime to rest your weary limbs. You will agree with me that that sort of a cure would suit many people, and I should be quite agreeable to go through it myself.—I am, Sir, yours faithfully,  
WOLFGANG ARNDT.

8, Carlton Vale, Maida Vale, N.W.

## Answers to Correspondents.

- \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.
- \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- \* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington Street, Strand, London, W.C.
- \* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

#### PHOTOGRAPHS REGISTERED:—

- S. H. Greenway, 27, Abington Street, Northampton. Two Photographs of the Mayor of Northampton.
- H. W. Graydon, 4, Christchurch Road, Southend-on-Sea. Photograph (Combination) of a Placed Group, containing Thirteen Men, being the Southend United Football Club, Season 1908-9.
- A. Rollins, 17, Shields Road, Byker, Newcastle-on-Tyne. Photograph of the Meeting of Champions, Victoria Grounds, Newcastle-on-Tyne.
- E. G. Harries, Alma House, Bishop Street, Londonderry. Photograph of Admiral Lord Charles Beresford, taken aboard "King Edward VII." at Lough Swilly, Ireland.
- A. G. Wallis, Commercial Road Post Office, Hereford. Photograph of Victoria Bridge and Hospital, Hereford. Photograph of Castle Green, Hereford.
- J. P. Jefferson, Bridge End, Peterborough. Two Photographs of A. J. Robertson International and National Cross-Country Champion.

VARIOUS.—(1) Can you please inform me as to which is the best book on micro-photography, and also the name of the publisher? (2) Do you know of any maker of gelatino-chloride plates, where, instead of the gelatine being on glass, it is on celluloid, and perfectly transparent when held close up to the eye?—T. TEASDALE-BUCKELL.

(1) A very good book on photography with the microscope is that by F. Martin-Duncan (Hazell, Watson, Viney, 1s.) On the making of minute photographs (which is usually described as

"micro-photography") there is no text-book. (2) We know of no dry-plate firm which makes a chloride or print-out film, though possibly you could get films specially coated with such emulsion.

**COPYRIGHT.**—Some time ago I was asked by a printer to take several photographs of interiors of a mill for catalogue illustration. I arranged to supply him with one print from each negative. This was done and paid for. Subsequently the printer asked me to quote for further copies. This I did, but I am afraid he stuck too much commission on; anyway, there was no order. Now what I want to know is, am I justified in offering copies direct to the mill-owner, or must I supply copies only through the printer?—**PTRO.**

If, as we take it is the case, you regarded the printer as liable to pay for the photographs in the first instance, then the copyright in the photographs is his, and you are not at liberty to take prints from the negatives or otherwise make use of the latter without his sanction.

**FIXING BATHS.**—(1) Please tell me the difference in effect between plain and acid hypo on plates, films, and prints. (2) Is acid hypo indispensable in either or any case? (3) How can I convert plain hypo solution into acid ditto, with economy and rapidity?—**ENTHU.**

(1) The fixing action is the same in each case, but is usually rather slower in the case of "acid" baths. The "acid" bath keeps clear as long as it is active, and prevents to a great extent, the greenish colour of negatives developed with pyro-soda. (2) Not indispensable in any of the cases mentioned. (3) By adding potass metabisulphite, about  $\frac{1}{2}$  oz. to each pint of hypo solution.

**GLASS CLOTH.**—Could you please tell me who are the makers of the canvas now so much used for wall decoration at photographic exhibitions, etc.?—**SCOTT GALLOWAY.**

We do not know a maker who supplies except through the trade. Better apply to studio suppliers, such as F. E. Jones and Co., 22, Gray's Inn Road, W.C.

**REND.**—The "St. Louis and Canadian Photographer," 911, N. Sixth Street, St. Louis, Mo., or "Wilson's Photographic Magazine," 289, Fourth Avenue, New York, U.S.A.

**T. PIKE.**—They are not made now, although they have spasmodically appeared on the market during the past fifteen years. The Autotype Co. could supply prints with similar effects.

**P.**—It depends on (a) the focal length of the portrait lens, and (b) the extension of the camera. The extension must be double the focal length of the lens. As you do not give us particulars we can only advise you to apply the above rule for yourself.

**DI-MCHROMATE.**—Would you favour me through the "Journal" with a full and reliable formula for the gum-bichromate process.—**J. C.**

"Formula" for the gum process invariably leave a good deal of latitude to the worker. We can best refer you to one of the text-books on the process, such as that by Maskell and Demachy (Hazel, Watson, and Viney, 1s.).

**STEREOSCOPES.**—Could you tell me if there is on the market a stereoscope very portable or able to be packed up and yet quite efficient and not too expensive. I wish to send one to a relative in Canada and the ordinary American pattern would be awkward to pack, and also liable to damage in transit, I fear.—**JEAN.**

All large dealers such as Houghtons and Butcher's stock folding stereoscopes. One known as the "Foldscope" is made entirely in metal and specially for travelling purposes.

**R. H.**—Not this year.

**BOOK ON ZINC ETCHING.**—1. Could you inform me if there is a book published with full instructions for making zinc blocks for newspaper printing? If so, where could I get same, and price? 2. Is there a sensitised zinc plate on the market?—**J. R. M.**

1. "Photo-Mechanical Processes," by W. T. Wilkinson, published by Hampton and Co., Cursitor Street, E.C. 2. It is usual to sensitise the zinc with a bichromated fish-glue mixture, but we believe a sensitised metal plate is to appear on the market. The inventor is Mr. Arthur Payne, of Mawson and Swan. Better write to him.

**BOOKS.**—1. A good cheap book on cinematograph management. 2. Book or books dealing with professional side of photography. 3. A

quick and cheap developer for portrait work. 4. Are combined baths much used by professional photographers? 5. Recommend a combined bath for portrait work.—**A NEW READER.**

1. "The Cinematograph," by Cecil M. Hepworth (Hazel, Watson, and Viney, 1s.). 2. "Professional Photography," by C. H. Hewitt, 2 vols., 1s. each, published by Iliffe. 3. Diamidophenol, purchased in quantity, forms a very cheap developer, but probably pyro-soda is as largely used as any other developer for portraiture. 4. Not largely by the better class of professional photographers. 5. As reliable formulæ as any are those given in the "Almanac" under "P.O.P. formulæ."

**MAKE OF LENS.**—Could you inform me what make of lens bears this trade mark (device)? There is no other mark on the mount.—**A DABBLER IN PHOTOGRAPHY.**

Without seeing the lens we are unable to say what make it is. We do not know the trade mark as sketched, but probably it is that of a dealer who sold it and not that of the maker.

**PAINTER.**—We believe you are liable for the fees, and you certainly will have to submit your plans to the district surveyor for whatever purpose the building is used.

**W. HALL.**—We do not know of any such book, but possibly some of the booksellers might be able to tell you of one. Write to Sotheran's, in the Strand, or George and Sons, 151, Whitechapel Road.

**LIGHTING OF STUDIO.**—Should be obliged if you would suggest a suitable lighting of studio by incandescent gas. Could I obtain good results for heads, three-quarters, small groups of, say, four persons, with eight incandescent mantles, or how many should I require, and what would be the best arrangement of same? I should feel extremely obliged if you would be good enough to put me right in this matter.—**CHAS. WALLACE.**

Eight burners could be used, but the exposure would be very long for groups, even if a lens with large aperture were employed. We should advise you to apply to the Tress Company, Rathbone Place, for a list. From this you will gain some information as to what is required.

**STUDIO QUERY.**—I bought a business here (stationery, etc.), intending to open up with photography, but cannot get my plans passed for studio unless I have all brickwork right round, which I cannot afford, so I think of converting a room upstairs into a small studio. I have enclosed a rough plan of room. 1. What lens is most suitable? 2. Which artificial light is the best? I have gas in the room. I have a half-plate, —'s, working  $f/6$ . I shall be pleased of any advice you can give me.—**A. E. NICHOLLS.**

1. The room you propose to convert into a studio is much too small for even medium-class work, seeing that the shortest focus lens made for cabinet portraits, full length, requires between camera and sitter the full length of your room. A lens with an aperture of  $f/6$  is, of course, slow for artificial light. 2. The electric arc light is the best for portraiture.

**APPRENTICESHIP.**—I beg to thank you for your kind and prompt answer to my enquiry re apprenticeship and agreement in the "Journal" of November 13. Might I ask a further favour? What should be a reasonable time given to an apprentice to be taught studio work, viz., lighting, posing, and dealing with sitters, also sepia printing?—**HILLIER.**

We should say that with a three years' apprenticeship the apprentice should receive practical instruction in studio work during two years, or at least eighteen months, of the period, as that is the most important part of the business. He cannot well be expected to become proficient in this part of the business in much less than a year if his whole time is devoted to it. Proficiency in the studio, lighting, posing, and the management of sitters is not learnt in a few months.

**A PATENT QUERY.**—I have recently bought the business of Mr. — under the hammer, which was sold through judgment in the High Courts. Among the tools is a midget camera with a numbering arrangement for numbering the sitters. I am now served with a writ from Mr. — to restrain me or my servants from infringing his patent. Will you tell me in this week's "Journal" if by using the camera I am infringing patent rights, as I fail to see in which way I am; also can they compel me to destroy the camera or deliver to them? I have always thought

that the patent granted was to stop anyone from making. I have not made or caused to be made this camera, but am only using in the ordinary way of business.—TRANSFERRED.

If the camera is patented you can be restrained from using it, except under licence from the patentee. You are under a misapprehension with regard to the patent law only applying to the manufacture of the apparatus; it also applies to the using of it, otherwise a patentee would have but little protection in his patents. Probably you can obtain a licence to use the apparatus for a small sum.

**COLOURING.**—1. Where may we obtain Raffaelli's solid oil colour pencils as mentioned in "Almanac" of 1907? 2. What is monochrome? Where may we obtain it? What does it cost?—OIL COLOUR PENCILS.

From any dealer in artists' materials, or from a London house, such as Marion and Co., Soho Square, London, W. 2. We know of no trade preparation sold under this name. The word is usually used to signify production of a print, etc., in one colour only.

**STOPPAGES FOR BREAKAGES.**—Kindly let me know if I can summon an employer for stopping my wages for breakage. No agreement was made, nor was it mentioned at the time, three months before I left. It was deducted from my last week's salary.—C. VALROSCHÉ.

You can certainly summon your employer, but whether you will recover is another matter. In your case we should say you will, seeing that no agreement was made with reference to breakages when you were engaged. If the accident occurred three months ago, and you have since been paid without deductions, we think you will be able to recover your full salary.

**MIDGET PORTRAITS.**—1. Formula for a hydroquinone developer that will give a hard, "contrasty" negative, and dense enough to give good bromide results. A developer suitable for both plates and paper preferred. 2. What method can I adopt for artificial lighting to take midgets (head and shoulders) other than flashlight where neither gas nor electric light is available? Is there any apparatus sold to burn petrol or acetylene gas; if so, where obtainable? Any hints on the lighting for above much appreciated. 3. Can you recommend a suitable lens for taking the above (12 on  $\frac{1}{4}$ -plate), moderate in price, fast, and for working in a confined space?—SCROGG.

1. The second hydroquinone formula given in the "Almanac," p. 771 (1909 edition, published December 1), will give great contrast quickly, and may be used for both plates and prints. 2. We know of no petrol installation which would be of any service. Acetylene is quite suitable. Better write to R. J. Moss, 98-99, Snow Hill, Birmingham, stating your requirements. 3. A C. de-V. portrait lens would be as suitable as any if its focal length does not require too great distance from camera to sitter. As a guide, we would mention that a head and shoulder, measuring, say, 20in., will be reduced on each small print to about 14in., a reduction of sixteen times. Therefore, with a 6in. lens the distance between sitter and lens will have to be about 8½ft. See the "Optical Rules," p. 932 of the 1909 "Almanac."

**POT. CHLOR.**—A formula of the kind is: Potass nitrate, three parts; potass perchlorate, three parts; magnesium powder, four parts; but better are the commercial powders, such as the "Agfa" of Chas. Zimmermann and Co. Moreover, the making of flash powder is not without danger. It is impossible to give an idea of the quantity, but for so large a space it would be half an ounce or more, laid in a train or narrow ridge.

**R. F. LUGG.**—We will reply to yours next week.

**PATENT QUERY.**—There is nothing to prevent you making carbon tissue for your own use, or for sale, if you desire. There are no patents now in existence in connection with the ordinary carbon process. We rather doubt if it will pay you to make the material for yourself seeing that excellent tissues are now marketed at a moderate price.

**STAFFS.**—Methylated ether will do quite well for thinning enamel collodion. Methylated spirit may also be used, provided its strength is not less than S.G. 820. If it is weaker than that there is the risk that the thinned collodion will give a crapy film.

The spirit should be free from mineral spirit. That which now known as industrial alcohol is what should be employed.

**H. R. COTMINGTON.**—The firm is a highly respectable one, and it is highly probable that the reproduction was made without knowledge that there was a copyright in the picture. We have little doubt that if the copyright is really yours, and if you the magazine, giving the date and number of registration, proprietors will arrange terms with you. We should advise you to do this before putting the matter in a solicitor's hands. If the picture is unique you should receive a fair sum by way of damages.

**G. SOLOMON.**—There is no fault in the lens with which the negative was taken. The cause of the cracked line at one side of the print is that the paper has been stretched in the mounting. That seen by the cut edge being crooked like the line in the photograph. Are you not aware that paper, when wet, can be stretched to a very considerable extent, and often produces distortion in the photograph?

**STUDIO.**—(1) You will have to submit plans of the studio to the local authorities and get their approval of them before you commence building, otherwise you may possibly have to take all the work when finished. The fact that the landlord has given you written permission to erect the building has nothing to do with local building laws. (2) The design for the studio is as good as could be desired, though it would be more convenient for work if it were a couple of feet or so longer.

**SITUATIONS IN FRANCE.**—Having the idea of going to improve myself in France, I am anxious to know of any French photographic paper which contains advertisements of situations vacant, such as appear in the "B.J." Should be glad to know name and price of same.—FELIX.

The best paper is "Photo Revue," 118, Rue d'Assas, Paris. You had better write for a specimen copy.

**"HOBBIES" CLUB FOR LONDON.**—Viscount Molesworth and Hon. George Scott (we read in the daily papers) have hit upon a new idea for a club. Assisted by an influential committee, they are negotiating for splendidly equipped premises in the West-End of London as a home for the new "Hobby Club."

Men will be admitted as members; women as associates. All men have hobbies, and, so far as the club is concerned, they must be amateurs. The club will cater for hobbies in: Science, travel, sports, curio collecting, physical research, carving, metal work, photography, gardening, book collecting, china, *objets d'art*, and recreations generally of busy men and women of position.

An extensive library will be formed on all subjects. Intellectual salons will be held, at which men or women of similar tastes may confer and aid each other. Experts will be engaged to lecture and give advice. There will be a department where members and associates may sell, buy, or exchange their *objets d'art*.

Already many well-known men and women with hobbies have given their patronage to the club, and Mr. Stuart Nuthall, at the temporary offices, 33, Wilton Place, will supply full particulars to those interested in it.

**\*\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

THE BRITISH JOURNAL ALMANAC.—The entire edition of 25,000 copies is now exhausted, and our publishers regret to announce that they cannot fulfil further orders.

A forecast of the probable results of the recent conference at Berlin on international copyright is supplied by a contributor in Germany, Mr. Richard Thirsk. (P. 904.)

Mr. W. Foster Brigham contributes a description of the method of card-filing suitable for controlling both working and book-keeping in a professional portrait business. (P. 905.)

Some points arising from the recent Inland Revenue prosecution of free-portrait canvassers are mentioned in an article on p. 902.

A most useful compilation of hints on portraiture appears in the American Annual of Photography," just published. (P. 908.)

Some interesting figures regarding German photographic trade with Portugal have recently been published. (P. 903.)

Mr. W. E. Debenham contributes directions for the making of carbon prints on ivory by the single transfer process. (P. 911.)

The use of gold chloride in the salting solution for plain paper is advised by a practical worker. (P. 910.)

The practical methods to be followed in using the carbon process lantern slides are the subject of an article on p. 903.

Photography in the study of metals is now regularly used by engineers and steel-makers. A description of the method employed is given on p. 912.

Mounting methods and dark-room lamps appear among patents this week. (P. 913.)

Blackpool photographers have banded themselves into an association, formed with the object of protecting photographers of that town against the "ravelling fraternity who visit it only for the summer months. (P. 913.)

## EX CATHEDRA.

### Bromoil and Acid Fixing-Baths.

A correspondent in a contemporary attributes some failures with the Bromoil process to the use of an acid fixing-bath. He developed with amidol, following with a fixing bath rendered acid with sodium sulphite and sulphuric acid, and after the Bromoil preparation had been carried out there was no relief whatever in the prints. On resorting to plain hypo fixing baths the trouble disappeared. In this particular case it is evident that the acid fixing bath was detrimental, but we believe some workers habitually use acid fixers without mishap, therefore there must be some special circumstances that require further consideration. In all cases of this kind there are many variable conditions. If a print is put into an acid fixer without rinsing there must be some kind of reaction between the acid and the alkali of the developer. This will differ with different developers, and varying products will be formed which may or may not interfere with the Bromoil preparation process. Then, again, there are different varieties of acid fixing baths. To arrive at the true cause it would be necessary to spend a considerable time in "ringing the changes" on all the possible variations, and only those who have attempted a similar course of experiments can realise how the number of possible variations seems to increase as the work progresses. We do not much believe in the idea that reaction between developer and fixer is the cause of the trouble, and we are inclined to think that the most important point to test first is the kind of fixing bath. The most popular form of acid fixer is a hypo bath, to which either potassium metabisulphite or sodium bisulphite has been added, but the one used in the case quoted was composed of hypo, sodium sulphite, and sulphuric acid. Though the last two constituents mentioned combine to form bisulphite, yet the final result is not the same as a bath to which plain bisulphite has been added, because a very large proportion of soda sulphate is formed. Whether this makes any difference or not we cannot say positively, but it is at the least a possible source of trouble.

\* \* \*

### Some Experiments in "Stereo-scopie" Relief.

Prof. Gustave Michaud describes in the "Scientific American" some experiments that have apparently led him to the conclusion that we can perceive relief in a single photograph if, by means of reflectors or other suitable aids, we can observe it with both eyes without converging the visual axis. This he considers to throw light on the "hitherto unexplained cause" of the relief seen when we examine a picture with both eyes through single large lens—in other words, through araphoscope, the action of which was very fully explained in an article

in our issue for April 5, 1907. The principal experiment described by Prof. Michaud is the examination of an imitation stereoscopic slide made up of two similar prints. This happens to be a good specimen, and it shows strong relief in an ordinary stereoscope. Instead of an ordinary stereoscope the Professor employs a piece of card with two half-inch holes in it exactly  $2\frac{1}{2}$  inches apart, and holding it in such a way as to facilitate the fusion of the two images, of course, obtains exactly the effect that is produced in a stereoscope. In fact, he uses a stereoscope without lenses. Of course, it is a fact that the visual axes are parallel when the effect is secured, but this does not prove that the suggestion of relief is due to their parallelism. On the contrary, as unsuitable subjects viewed in precisely the same conditions will not readily give any suggestion of relief at all, it appears evident that the effect when obtained is due to something other than simple parallelism. In the example shown the prints are trimmed like true stereo prints, and appear to stand behind the surrounding paper, which condition, as we have often pointed out before, will very frequently give a suggestion of relief in the subject itself. Another experiment of the Professor's is the examination of a single picture by the aid of apparatus that enables both eyes to see it from practically the same view-point through a small pinhole. Given true perspective and a small view-point at the right place strong relief can always be obtained with one eye, and if we can arrange matters so that both eyes view the picture through what is virtually the same pinhole we should expect a similar effect, somewhat more realistic because the conditions are more natural. Prof. Michaud gives no reason why parallelism of the axes should suggest relief, and he apparently overlooks the fact that in ordinary vision strong convergency always accompanies strong relief, while parallelism is associated with absence of relief. He is apparently trying to evolve a general rule from a few very special cases which already admit of far simpler explanations.

#### HAWKERS, PEDLARS, AND CANVASSERS.

THE article in our issue of October 23 on the Inland Revenue prosecution at Worcester of "free portrait" canvassers under the Hawkers Act has brought us a number of letters from photographers who have been interested in this new aspect of the canvassing frauds. Several of our correspondents are apparently under a misconception of the law controlling the doings of the traders described as "pedlars" and "hawkers." One correspondent writes us that on conferring with the police authorities of his town he is informed that no action can be taken in the case

of canvassers who fill orders for frames from samples which they exhibit—that, in fact, such persons are exempt from the Act and do not require a licence. That such, however, is not the intention of the Acts relating to the selling of goods from door to door is shown by the following passages:—

#### Pedlars Act, 1871.

"The term 'pedlar' means . . . any person who . . . travels, . . . carrying to sell or exposing for sale any goods, wares, or merchandise, or procuring orders for goods, wares, or merchandise immediately to be delivered, or selling or offering for sale his skill in handicraft."

#### Hawkers Act, 1888.

"'Hawker' means any person who travels with a horse or other beast drawing a burden . . . carrying or exposing for sale any goods, wares, or merchandise, or exposing samples or patterns of goods, wares, or merchandise to be afterwards delivered . . ."

That the phraseology here employed as to the sale of goods by sample is not used inadvisedly is shown by the further specific exemption of "persons selling or seeking orders for goods, wares, or merchandise to and from persons who are dealers therein, and who buy to sell again." It is therefore evident that the Acts applying both to hawkers and pedlars cover the modes of business adopted by the "free portrait" canvasser.

As regards the recent prosecution at Worcester, it is quite correctly pointed out by several correspondents that it was instituted, not by the police authorities, but by the Inland Revenue Department at Somerset House. While the supervision and register of pedlars and hawkers is very properly assigned to the police authorities, prosecution of a person for house to house trading without licence must naturally come from the Inland Revenue Department. Yet it is not correct to say, as one correspondent informs us has been said by the police of London, that the police authorities are powerless to move the matter. It is within our own recent knowledge that such interference has been made by the police in the case of photographers who were carrying on a genuine photographic business by soliciting orders from door to door. Such photographers have frequently appealed to us, asking if a pedlar's licence was needed by them, and in most cases we could not inform them that their business was done in such a way as to render a licence necessary. Therefore, while we point out that a law officer of the Crown is the one to appear as prosecutor of these canvassing gentry who come within the scope of the Acts, the police authorities are exceeding by very little, if at all, their legitimate duties in seeing that the law as to

### THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1909.

Edited by GEORGE E. BROWN, F.I.C.

#### NOTICE.—IMPORTANT.

OUR publishers ask us to inform agents that the entire edition of 25,000 copies of the "Almanac" is now booked, and they regret being unable to execute further orders.

The forty-eighth annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published on December 1. This year's ALMANAC reached a total of over 1,000 pages, and the entire edition of 25,000 copies was sold out immediately. Of no other photographic book ever issued can two such unique facts be recorded. The edition for 1909 will also consist of 25,000 copies.

The editorial article will deal very completely with the important subject of

#### REFLEX CAMERAS,

and the systematic review of the work of the year under the title "Epitome of Progress" will be a strong feature of the volume.

The lines followed in the previous editions of the ALMANAC will be maintained in general, but in a number of particulars the arrangement of the volume for 1909 will be modified to make it more than ever the book of universal photographic reference.

The ALMANAC for 1909 will appeal to photographers all over the world as a daily reference guide in practical work. The standard matter and formulae will be revised and added to where necessary, and, wherever practicable, new features of an informative nature will be added.

taking out of a licence is not disregarded, and it was on this account that we suggested to our readers that they might bring the facts before the local authorities in reasonable certainty that the latter would themselves take or advise the taking of the further necessary steps.

### GERMAN PHOTOGRAPHIC TRADE WITH PORTUGAL.

We are constantly calling attention to the fact that English manufacturers of photographic materials are gradually being ousted out of the foreign markets by their German competitors. That these statements are not founded on mere surmise, but belong to the realms of fact, is proved by nearly every statistical report that comes to us from countries abroad. A comparative study of these statistical reports, which may be found among the various Consular Reports published by the Government, should prove a very valuable object lesson to some of our manufacturers, and doubtless stir many of them into action where at present there is too much of the tendency shown to rest on their laurels. From these reports we learn something of the growth of exports of German photographic materials to the various countries using such articles. They prove the German's readiness to adapt himself to the various conditions of the countries to which he exports. In nearly all instances the exports show a steady increase, while in some cases the rapidity with which they have secured the markets is astounding. We are not prepared to say that this increase has always been to the detriment of English exports, for one must always make allowance for the increased demand there is for photographic materials, yet there is more than a suspicion that much of the trade at present going to German houses would be retained by English manufacturers were other methods employed, possibly more pushful methods, similar to those adopted by the Germans.

The latest statistical report comes from Portugal. From it we learn that Germany has supplied more than 40 per cent. of the apparatus, cameras, etc., and of the photographic papers imported into Portugal during the past year, while the same country has sent a fourth part of the plates used during the same period. Here are the figures and the prices paid for the various articles:—

#### Apparatus.

The whole import, 1,040 pieces=18,688 Milreis.  
Of these, imported from Germany, 358 pieces=7,654 Milreis.

#### Plates.

The whole import, 37,618 kilograms=23,225 Milreis.  
Of these, imported from Germany, 10,050 kilograms=5,822 Milreis.

#### Photographic Papers.

The whole import, 15,968 kilograms=17,382 Milreis.  
Of these, imported from Germany, 3,685 kilograms=3,929 Milreis.

These figures show a decided increase in German imports into Portugal as compared with the previous year. And it must be kept in mind that Portugal is one of the least favoured countries for German enterprise. In consequence of high tariff restrictions against Germany the trade of the latter country is hampered, and has not been able to advance in Portugal at a corresponding rate to its advance in other countries. At the present moment the German authorities are negotiating with the Portuguese with a view to abolishing these restricting tariff walls, and it is expected that before long a treaty will be arranged whereby Germany will come under the Most Favoured

Nations Tariff Clause. This will mean a general reduction on all goods imported into the country; in some instances the reduction will be as much as 50 per cent. This is a point well worthy of the English manufacturer's most careful attention. If he is not to lose ground entirely, he must take time by the forelock and make his place in these markets more secure while there is yet time. It stands to reason that whenever this new treaty is accomplished he will experience more keenly than ever the pressure of German competition. This is not the time to discuss the superiority or the inferiority of the goods manufactured by either nation. Much more practical results will be obtained by doing as the Germans do, and making thorough and careful investigations on the spot to find out exactly what the market requires, how it requires it delivered, to have men on the spot whose interest it is to push trade, and, most important of all, to see that the market is supplied with exactly what it requires.

### LANTERN SLIDES BY THE CARBON PROCESS.

MUCH as the working of the carbon process has become familiar among amateur workers, the use of carbon tissue has scarcely made the progress which the fine results deserve, but the advantages of the pigmentary slide from the point of view of fixity and purity of colour surely require no special emphasis, and in the belief that many slide-makers entertain a mistaken idea as to the extraordinary obstacles in the way of carbon for transparency work, we may well pen a few practical hints on the working methods, and such is as good a course as any to show the simplicity of the process.

A stock of glass plates of the standard size ( $3\frac{1}{4} \times 3\frac{1}{4}$ ), free from air bubbles and other defects, are thoroughly cleaned and then coated with the following substratum:—

Nelson's No. 1 photographic gelatine...	1 oz.
Water .....	25 oz.
Bichromate of potash .....	1 drachm.

The gelatine is dissolved in the usual way, and the bichromate is added afterwards. The solution is then strained through fine muslin, and, at a temperature of, say, 120 deg. F. is forced over the plates, which are then placed in a draining rack and allowed to dry spontaneously in full light, and in a place free from dust. It goes without saying that any particles of dust in this coating would show more or less when the finished picture is projected on the screen. A good stock of plates may be prepared at a time, as they will keep indefinitely if stored in a dry place. It is quite possible to develop the prints on unsubstratumed glass, but there is then some difficulty, except in the hands of experienced workers, of retaining the delicate tints in the lights, and other minor troubles may arise in the working. Furthermore, there may be the annoyance of the carbon image splitting off with the heat of the lantern if the slide is long exposed to it. In practice, therefore, the slight trouble involved in substratuming the glass is well expended.

The tissue may be sensitised in the usual way, but for our present purpose it is as well to proceed as follows:—Glass plates are cleaned, and then rubbed over with French chalk. A convenient size to use, if a number of slides are to be made, is fourteen inches square, as that will allow of sixteen pieces being cut from the sheet of tissue. The cleaned and chalked glass is next coated with thin enamel collodion—ordinary enamel collodion, thinned with about a third of its bulk of equal parts of ether and alcohol, is very suitable. After the collodion has well set, the plate is put into a dish of clean, cold water until the apparent greasiness of the film is washed away. The plates are then taken out and stood up to drain, but not to dry. The

tissue, cut a little smaller than the glass, is sensitised in the ordinary manner. A good bath for this time of year is as under:—

Bichromate of potash .....	1 oz.
Liquor ammonia .....	1 drachm.
Water .....	20 oz.

The solution, which may be employed several times, should be filtered or strained through fine muslin before use, to remove any particles of foreign matter it may contain, which would otherwise show when the finished slide is thrown on the screen. The tissue is immersed in the solution for from two and a half to four minutes according to the character of the negatives to be printed from. If the latter is thin and feeble, the shorter time will be ample; if strong and vigorous, the longer time should be allowed. The tissue when taken from the solution is laid on the collodionised plate, and then squeegeed in contact, avoiding air bubbles as a matter of course. The glass with the adherent tissue is now placed where it will dry in from six to eight hours at most. The advantage of drying tissue in this way is that the surface is thoroughly protected from dust during the drying, and also from injurious atmospheric influences, which might produce a surface veiling, or fogging, that would impair the brilliancy of the picture on the screen. When the tissue is dry, it, with the adherent collodion, can be stripped from the glass, when it will have an even and brilliant surface, so that perfect contact with the negative can be ensured. If the tissue is not to be used at once, it had better be left on the plate, as it will then be protected from the air, and, therefore keep good a longer time.

In printing, the negative must have the usual safe edge. A lantern slide mask answers admirably, and for convenience in the working, it may be attached to the negative water, and then squeegeed on the substratum glass, which adhesive can at any time be removed, leaving the negative just as it was before. A convenient way of cutting up

the tissue is to have a glass plate, say, three and an eighth of an inch square, then there will be no difficulty in getting the tissue in exact position on the negative, or on the slide glass for the development. The exposure should be a full one, but not nearly that required for transparencies for enlarging from—about a third or so more than would be given if the picture were to be on paper will be about right, for it should be kept in mind that the extreme high-lights must be represented by quite bare glass.

After printing, the exposed tissue is soaked in cold water, and then squeegeed on the substratum glass, which should previously have been put into the water for a few minutes. The soaking of the tissue, however, should not be quite so long as in the case of paper prints. After mounting, the plates are allowed to stand for the usual time before development. The development is done in the ordinary way—the water being at about the usual temperature. But if the tissue has been over-exposed, it may be considerably increased and the development continued, until the highest lights appear as bare glass when the slide is laid on white paper. When the development is completed the slide is put for two or three minutes in about a five per cent. solution of alum, and then washed. The washing, after the alum, should be more complete than is actually necessary for paper pictures, for if any of it remains in the film it might crystallise out, and perhaps mar the brilliancy of the picture when seen on the screen. Varnishing is not actually necessary, but in some instances it gives somewhat more transparency to the image.

The method just described may seem a little more troublesome than that of the usual way of working the carbon process, but the trifling extra trouble is worth taking, as the substratum glass and the collodionised tissue free us from such little vexations as reticulation, washing away in the high-lights, etc., should the tissue not be in exactly the best working order. The picture will also bear somewhat rougher treatment, such as hotter water and the like, in the manipulation.

## THE BERLIN CONFERENCE ON COPYRIGHT LAW.

AFTER nearly five weeks' discussion, the Berlin Conference, which was called to revise the Berne Convention, as it is applied to literature and artistic productions, under which latter heading photographs are included, has at last come to an agreement. This was signed on the evening of Friday, November 13, in the Reichstag Building, in Berlin, by fifteen delegates from countries within the Union, and by twenty delegates from countries not yet included in the Union. This agreement has not yet been made public, but I have had the favour of glancing through a rough draft taken from it. This draft did not by any means profess to give the full wording of the text, yet I have been unable to discover in it any new conditions or other agreements that are likely to cause any particular change or alteration in the International Copyright Laws as they are at present applied to photography. As yet no provision has been made for fixing a uniform time limit to the duration of copyright after the decease of the holder within the various countries embraced in the Union. Therefore, we still have the fiasco of an international law which in one of its most important points is not international, since it fixes its time limits according to the whims or the advantage of the various countries which have agreed to it. Thus far the Berlin Conference may be said to have been a failure. It is only on reading between the lines that we discover that the delegates have not been empowered to settle this all-important clause on their own initiative, though as a result of their deliberations they have promised to see that the

matter receives the most careful attention of their respective Governments, and in this way at some future date some sort of an agreement may be come to. The proposal of the Berlin Convention to fix the copyright limit at a period of fifty years after the death of the copyright holder was objected to by some delegates on the ground that such a regulation would entail considerable changes in the existing copyright laws in their countries. Germany, for instance, would not agree to a longer period than thirty years, which is the present limit. Therefore, as I have said, the Conference came to the unsatisfactory conclusion that the individual delegates were to do their best to influence their Governments to arrive at some sort of uniformity. As this clause stands at present, it cannot be said to be strictly international, since we have the anomaly of an article going out of copyright in the country to which it originally belonged, and yet still retaining copyright in other countries embraced in the Union, or, as the case may be, *vice versa*.

In other respects the Berlin Conference has been able to clear up many doubtful and uncertain points, which will lead to a clearer understanding and the smoother working of the Berne Convention, since it rids its somewhat cumbersome machinery of many of the almost impossible obstacles that in many instances rendered it somewhat impracticable. When the new agreements come into operation in July, 1910, photographers will know more exactly in what position they stand regarding the law, and what amount of protection it affords

them. The Conference has widened the application of the International Copyright Act, increasing its usefulness, and at the same time it has defined more distinctly the various works which are protected within the meaning of the Act in the different countries. Over this point many disputes have arisen in the past which could only be settled by precedent, and even then not always satisfactorily.

#### Protection for Cinematographic Films.

Among the articles to which absolute protection is to be granted, photography and all kinds of choreographic art, meaning all allied arts or manufactures to photography, are the last mentioned. Against the inclusion of the works of applied arts under this head the British delegate raised objection, and consequently the matter still remains to be settled.

One point of which the Conference did not lose sight is the entirely new situation that has been brought about in various directions by the most recent advances in science. And this is a point which, if it does not directly concern photography—which is not yet quite clear—is at any rate immediately aimed at cinematography. The article expressly says that all copyright works are protected against copying or production by means of the cinematograph. The clause also goes so far as to prevent the copying or combining of protected incidents or scenes and the using of such as originals for cinematograph impressions, or pictures, or in any other way infringing such copyrights.

#### No Protection for the Journalistic Author.

It may be interesting to some to note in passing that the new reading of the law as it is applied to literature is that newspaper articles are not copyright, and may be copied or printed by those who choose to do so, the only condition being that they are to mention the source from which such articles are taken. Even the special articles by the foreign correspondents are free, though there was much dispute over this. In fact, the only things that are copyright in a newspaper are the serial novel and the short story. This seems like very unfair dealing with the journalist in making such a distinction between him and the short story writer, and is certain to call forth strong opposition from the members of the Fourth Estate, who will doubtless want to know why they are to be thus deprived of earning all the profits of what is often the result of days and weeks of weary toil.

The Berlin Conference is the second Conference that has taken place since the Convention was signed at Berne in 1886.

The last Conference was in Paris in 1896, by which it may be seen that a Conference is held almost every ten years, and it is practically certain that the next Conference, after the lapse of another ten years, will be held in London. At these Conferences the various difficulties that have been experienced in the working of the Copyright Act and the complications arising by the introduction of appliances and inventions introduced since the last meeting, are dealt with, and put as far as possible on a business footing. As I have already hinted, most of the new laws and regulations passed on this occasion refer to very trivial details, so far as the photographer, the postcard manufacturer, and all who employ photography in any shape or form for the production of pictures, are concerned. One great benefit which is sure to result from the Conference, and which should not be overlooked, is that since the lines of demarcation are more sharply defined it will be more easy to lay firm hold upon infringers. The knowledge of this on both sides will make the rights of copyright holders more than ever respected, and should succeed in putting an end to those flagrant cases of piracy that have only too frequently been brought to notice in the past.

#### Forthcoming Publications.

That the Conference was business-like in its methods is proved by the fact that it is going to be business-like in the distribution of its conclusions and deliberations. In order to prevent any overlapping or mistakes arising out of the complicity of Acts passed by various Conferences, which may in any possible manner be employed to the disadvantage or hindrance of the Convention terms, the Berlin Conference has decided to print in the languages of the various countries within the Union the new rules and regulations which were signed on Friday last. This new text is to replace all former texts or editions. By this means also the various countries which have not subscribed to the Berlin Conference on a few points will have an opportunity of comparing the old laws with the recent changes in them, and it is possible that this may lead to the adoption of some definite and united action in the settlement of these disputed clauses or innovations. Many things may happen between now and the ratification of the new agreements in 1910, and it is hoped that before then the different countries forming the Union will have come to some understanding and have found some common basis on which the Copyright Law may be established, and become more truly what it professes to be, an International Copyright Law.

RICHARD THIRSK.

## THE CARD-FILING SYSTEM FOR PROFESSIONAL PORTRAIT BUSINESS.

MANY of the most progressive commercial houses in the country have during the last few years supplanted the old system of keeping in books notes, addresses, and much other information, by the modern plan known as the "card filing" or "card index" system. This system could not possibly have found a place in the great mercantile offices without possessing advantages over the old-fashioned but familiar method, and therefore it appears only right that a short description should be given explaining the application of the system to the photographic business.

It is unfortunately a fact that the generality of studios are extremely lax in the matter of keeping records, but this may easily come about by the cumbersome nature of the usual account book, and the number required, besides the difficulties of finding an entry when made. These drawbacks are quite overcome in the card system, perhaps its greatest advantage being the ease with which any entry made at any time can

be instantly located, even though it be included with thousands of other items. Other advantages, almost as great, are the small space occupied and the fact that there is no waste room, and that all information relating to the different entries is together, and can be easily and immediately isolated from other matter without disturbing any unrequired information in any way whatever.

This great superiority over the book system, in which indexing would mean many blank pages, the impossibility of removing any item without destroying the book, and the probability of matter relating to the same subject being scattered over two or three volumes, is secured by placing each entry and the details connected with it on a card by itself, entirely separate from any other information. The cards are easily handled, and it is obvious that they can be easily destroyed without interfering with any of the others, so that any useless matter is immediately done away with, instead of occupying

room and increasing the difficulty of locating other items as dead matter does in a book. There is, however, as we said above, no difficulty in locating these cards, since it is perfectly easy to classify and sub-classify in any way required. This is done by collecting the cards into groups and placing this group in front of what are known as guide cards. The groups can then be divided, and yet again sub-divided, in such a way that it is possible in a collection of ten thousand cards to have them so indexed that only a group of ten or twenty need be glanced through to find any desired information.

#### The Card Index for Address File.

To obtain a more concrete example, suppose the information is a collection of customers' names and addresses. The card having these details filled in would be placed in front of a guide card bearing the same initial as the surname of the client. In a large business these names, alphabetically sorted, would be further placed in groups representing divisions, or even streets, of the town. This is seldom wanted, however, by photographers, the alphabetical list being quite sufficient for most businesses. Of course, the cards are placed in correct sequence in front of the guide cards—"Ace" before "Addy," for instance. Should the number of names under the simple letters become too numerous for easy reference, it is an easy matter to add additional guide cards, so that instead of one there may be any number from two to twenty-four. A sub-division of three would mean replacing the simple initial by three others, such as Ab, Ak, Al, An, Ao, Az. At the same time, it is not essential to divide the cards into twenty-five parts, but in the case of a few specialised cards numbering about fifty it might be divided into five only—A-C, D-G, H-L, M-R, S-Z. In fact, using only the alphabetical system, the most useful for photographers, there is no end to the guide cards that can be used, with consequent ease of reference, sets comprising divisions of the alphabet into 60, 120, up to 3,000 parts being obtainable. It is, however, perfectly feasible to classify names under profession, or, as mentioned above, counties, towns, parishes, and streets, and then again to alphabetically index. Say in a large collection of names to which advertising matter is to be forwarded, the names might be placed before guide cards bearing the name of street, and then each name sorted according to surname.

#### Requisites for Card Indexing.

Before going more fully into details, it will be as well to consider the requisites of the process. The cards themselves may be of any size, but are preferably 4 in. by 6 in. or 5 in. by 8 in., these being standard sizes, and may be of any thickness, ordinary postcard substance being very durable. These cards can be obtained from the printers, who will also rule and print, as this varies according to requirements. Some guide cards with a single broad blank tab standing about half an inch above the other cards, and also some alphabetical guides with five tabs to the length of the card, are wanted. A set of twelve monthly cards, and two or three sets of thirty-one daily cards are a great convenience, and expand the system in a most useful way, as will be shown hereafter.

These cards should be provided with a case that will just allow the card to be stood in perpendicularly. These can be made by the local carpenter, or obtained as trays or cabinets with several drawers from the firms dealing in these goods. If the standard sizes given are adhered to, there will be no difficulty about that. The home-made cases should, however, have a wedging device, so that when the drawers are not full the cards are still kept upright. This is not difficult to arrange. It is advisable, however, to purchase a well-made case, as they make a nice addition to an office outfit. One word more. The systems on the market are often provided with rods that go through the cards and hold them in position. This we find a needless and rather troublesome refinement.

#### Systematic Record of Studio Routine.

We wish to show in this article how (except for keeping petty cash and goods accounts) the whole details of a studio can be kept by the card system, so that every item, from the first making of an appointment until the negatives are packeted, can be placed together and be immediately referred to at any time.

The suggested card for this purpose is shown: we have found it very satisfactory, though minor details can, of course, be altered. When hands are continually changing, it might be advisable to have details, such as name, proofs sent, remarks, packets, etc., printed in the spaces, and we have for the purposes of the illustration entered them, though in the usual way they are not required.

Taking the card as an example, it is noted that on Monday, January 16, an appointment was made by Mrs. Chas. Watson, of 62, Crown Terrace, for 2.30 on Wednesday, the 18th. The name is entered as shown, so that it is easily found when filed with others in front of guide card W. This appointment card should now be placed in front of guide card Wednesday, other appointments being in front of the other six days referring to them. Of course, should no appointment be made, the name and address only need be written on card.

On Wednesday, the receptionist will take out all the cards for that day, and have a simple guide to the day's expected sittings. Whilst the sitter is in the dressing-room the operator will receive the card, and from it will see the name of his sitter; this in itself is a considerable advantage, for operators frequently never have this, and can only locate their subjects by descriptions such as "The lady who drops her aitches," or other

Watson Mr. Chas	Until 20 <sup>th</sup> 62 Crown Terrace
Mon Jan 16 06	Permanent: 17 Portoboro Road
Wednesday 2.30	Baling
Thursday 12.00

Proofs ret. 2.30	Carbon 1/2 Imp
Packet 21 <sup>st</sup> 37	Mr. Bales. Mentioned
1/2 1/4 H 22	Miniature
Cream Mounts. Sepia Carb. Reduce 1/2	
hand. Position 4	Position 3 favourable.

Fig. 1.

equally vague indication. For his information the styles chosen have been filled in—oval cabinets, three-quarter and head, also the fact that there will be a change of costume; this saves much material, for often enough, after supposedly finishing a sitting, the client calmly mentions another dress. The query after carbon means that this is probable, but to be decided when order is given. The other matter in this space is occasionally valuable, for the receptionist can in this way give the operator hints picked up from the sitter. In this case he would take a somewhat similar Imperial (1-1) "on spec."

One often hears expressions of delight with certain types of work, such as coloured Cosways, semi-tints, enlargements, as in this case miniatures. This note will associate the most liked work with each customer, and when finishing the order a polite letter to say that "such and such a position will make a beautiful miniature, which we shall be glad to quote for," often means an increased order. When sending out booklets or personal letters, an appropriate one sent to old customers dealing with what they are known to like is worth

desire of the winner, and it is given for the best paper read or published during the year from July to July. Full particulars may be obtained from the Hon. Sec. of the London and Provincial Photographic Association at 43, Whitta Road, Manor Park, Essex.

## HINTS ON PORTRAITURE.

[In the 1909 "American Annual of Photography," just prepared with evident care by J. W. Little. There being such epitomised opinion is welcomed as an aid in their own study of portraiture, we may print here the first portion of the contribution, holding over the conclusion until next week.—Eds. "B.J."]

WITHOUT further preamble, I desire to explain that while many of the suggestions below are the result of personal experience, the greater part of them are from the experience of others, and have been drawn from numerous sources of which I hereby make a general acknowledgment. The preparation of this compilation, however unsatisfactory or incomplete it may be, has involved a considerable amount of labour, and I offer it to the readers of the "American Journal of Photography" in the hope that it may at least be found useful for occasional reference, even though many of the suggestions contained therein may not be unanimously accepted as good practice. Reference to photographing groups, genre subjects, and to the general subject of composition, has necessarily been omitted for lack of space.

The lines of a portrait should usually lead toward the face; they should also agree in sentiment with the character of the sitter; that is, they should be soft and flowing, or rugged and pronounced, as the subject may seem to require.

There should be variety and curves in all the lines of the figure. The arms should not hang loosely and slovenly, but should be arranged naturally and show opposition to the lines of the body and accessories. In standing portraits of women, the arms should usually be so placed as to show full curvature of the waist.

Shallow festoons, and arrangements following their lines, produce a light, cheerful effect, while deeply drooping festoons and constructions upon their lines, give a heavy and solemn effect. From this may be derived a hint as to the best methods of posing and the character of the accessories suitable for various classes of subjects.

Angles have a separating effect; hence angles entering deeply into a figure or group should often be avoided or toned down, or they may be obscured by drapery, etc. In other parts of the portrait pronounced or awkward angles may often be obscured by other means, as by a background which produces little contrast.

Right angles should usually be avoided in drapery and accessories, but may be admitted in architectural features. For this reason clothing of pronounced pattern, as large plaids or checks, is difficult to arrange satisfactorily.

The general arrangement of the drapery, like the pose, is often best waited for, rather than by the operator attempting to effect it.

The outlines of the figure should not be everywhere visible, but portions of it should blend into the background and shadows. Nothing should be allowed, however, to abruptly cut off any portion of it so as to make it appear too thin or as severed from the body.

A portrait should show connection with the sides of the picture, either positively or suggestively; that is, the mass of the figure or some portion of it should touch the sides or stretch in that direction, or it may be joined to the sides in some manner by the accessories. Where this is accomplished by a horizontal line extending across the portrait the line should appear to be continuous, and join with the figure at directly opposite sides, although it may run diagonally. The joining of the figure with the sides may also often be satisfied by the use of shadows or by a suitable background; the effect may even be produced by gradation in the background.

The spaces intervening between the portrait and the edges of the print should not be uniform or consist of rectangular or

triangular outlines, but should be broken up into irregular spaces, either by the pose of the figure or by the accessories.

In getting a good line in the head and shoulders, where space will permit and the lighting is under control, it is often better to travel around the sitter rather than to attempt to attain the result by having the sitter turn his head; or the sitter himself may be asked to move to various parts of the room.

When the head and body face the camera, the suggestion is of rest and repose. When turned in a different direction from the body, there is a suggestion of movement and animation; usually this is the more satisfactory.

### Balance: Symmetry.

If a figure is required for the middle of a panel, and the body is turned to one side, the head may be turned to the other to give balance and symmetry.

A three-quarter view of the head is sometimes preferable to a profile in a decorative picture.

In a bust portrait, the head may sometimes be inclined forward somewhat, to diminish the contrast between the size of the head and the bust, but a lens of short focus should not be used, or distortion will result.

Stout people are usually best posed more or less in profile, both for head and shoulders. A seven-eighths full face is usually satisfactory, but a three-quarter face is apt to look baggy. They should usually be taken sitting, with but little of the figure showing, and outlines subdued as much as possible by any means which may be expedient.

A fat face should be placed close to the light, in order to get strong shadows. A thin face should be placed farther from the light, to secure roundness; the lighting should also be broader.

Trimming close to a bust tends to make the person look larger by contrast of lines.

In taking full length portraits of men, the weight of the body should usually not rest equally on both feet.

Old men should usually be seated; young men may be standing.

Old age generally requires a more vigorous lighting than youth; that is, the lighting should be more contrasty.

Old people generally look better against dark backgrounds; young people against light backgrounds.

Give full exposure for old people and develop for softness.

### Child Portraiture.

In child portraiture, the operator should keep his own head on a level with the camera so that the child, which is usually inclined to look toward the operator, will not lift the eyes too high.

When children are taken standing be careful that the lower edge of the background or the baseboard of the wall does not come exactly on a level with the lower line of the dress, which is likely to occur with short dresses.

It is hard to pose children in any special position, and it is therefore usually better to allow them to assume natural poses for themselves and await a favourable opportunity before releasing the shutter.

In a well lighted studio, instantaneous photographs of children may be taken by using rapid plates, a lens working at large aperture, and a focal plane shutter.

Puppies, parrots, kittens, soap bubbles, toys, etc., are useful

attracting the attention of young children and diverting them from the fact of their being photographed.

A very young child, to avoid the necessity of holding it, may often be more easily photographed at home than in a studio, where the surroundings are strange to it. At home it may be propped up in its pillow or crib and more easily controlled though the lighting may not be so good.

As the element of mystery, so often useful in other compositions, is of little use in pictures of children, they may well be taken in a strongly lighted or open air studio.

To avoid frightening children, the camera may often be concealed from them or even located outside the studio proper.

Young people, or those without pronounced character, should or be too sharply focussed, but the focus should be rendered soft.

When small children are photographed at home, it is often better to place the camera directly in the window in order to get broad lighting and so lessen the exposure. The blind, if light coloured, may also be raised overhead and extended horizontally into the room and used as a reflector. Older persons with pronounced features which cannot be well lighted may often be treated in this way with advantage also. The lighting by this method is of course necessarily flat, but may be controlled somewhat by the use of light and dark screens. Generally speaking, this method of lighting is not recommended except in cases of emergency, as where the light is poor, the lens slow and necessarily of short focus to get the subject sufficiently near the window.

When photographing children outdoors, orthochromatic plates, and if possible a light ray filter, should be used to get better flesh rendering.

### Figure Portraits.

Tall people may be made to appear shorter by giving more space above the head. Short people may have the head nearer the top of the print if it is desired to conceal their shortness of stature.

It has been recommended that an effective way of treating short lady standing is to use a polished wood floor, the reflections upon which produce an elongation of the vertical lines of the figure; that the effect of polished wood can be produced by having the floor covered with linoleum and wetting it previous to the exposure. This might be useful, but is hardly always expedient.

If the dress is long enough, a short subject may stand on a block of wood or a book an inch or more in thickness to increase her height somewhat. Another way is to place beside her a low chair, which will increase her apparent height by comparison.

Correct drawing cannot be obtained under six feet distance between the subject and the camera, and this distance should be considerably greater if possible, particularly for large faces, to prevent distortion. Full figures in rooms look better if they can be placed at a distance of not less than fifteen feet, to give better perspective.

In raising or lowering the camera in taking full figures, due regard should be had to the effect on perspective; that is, producing a low or high horizon or vanishing-point.

The legs of men in a standing position are often better left out. Three-quarter views of men standing are also difficult.

In a seated figure the lines of the arms should not follow too closely the lines of the arms of the chair.

### Expression.

Never have bald heads face the camera squarely or look downward.

It has been recommended to use a blue ray screen over the lens when photographing a brunette dressed in white.

A dark person should usually have a stronger lighting than a person of light complexion.

Brunettes usually look better in broad lighting; blondes in white may look better in shadow lighting.

The hair and face should harmonise in the photograph; that is, a blonde face should not appear to have dark hair nor a brunette face to have light hair. This calls for discrimination in lighting and in the use of light screens, and in many cases the use of orthochromatic plates and ray filters.

For coloured people, use a very dark background.

If a fair person be placed in a strong light, the contrasts between the lighted and shadow sides of the face are increased. For the same reason the background should not be too dark.

It is difficult to get strength in the eyes of a fair person in full face position. Blue eyes should be in shadow if non-orthochromatic plates are used.

The eyes should be directed in the general direction toward which the head is turned; that is, the direction of the gaze should be natural and not contrariwise. Up-turned eyes give a stupid expression.

The eyes should not ordinarily look directly at the camera, even in full face position, but the subject should always have some object back of the camera upon which to fix the eyes, to prevent staring.

A good eye rest consists of a large portrait so arranged that it may be moved to any position. The print should not be one of fine detail, but rather one which can be well made out at a distance.

Prominent eyes should be turned away from the camera. Deep set eyes require diffused lighting.

Small eyes may look upward somewhat or the chin may be depressed, leaving the gaze horizontal; large eyes, contrarily.

If the eyes look downward, some claim that the hands should be included in the portrait.

If one eyebrow is higher than the other, it may be turned away from the camera so that its greater height will not be emphasised.

If one eye is larger than the other, usually take the larger eye, to give better perspective. If the lens is of short focus, however, the reverse should be done if the exposure is made at close range.

If the exposure be long enough, the subject may blink the eyes, to avoid a strained expression.

Where there is puffiness in the eye, or a double chin, rub on a little yellow powder with chamois skin. This may also be used effectively on a bald head or on white hair mixed with gray.

To get an effect of action, the exposure may be made before the subject is fully posed. The operator may use a long tube and keep the bulb in the hand behind the back and out of sight. If a three-quarter or other view is wanted he may move himself to the desired position and have the subject look toward him instead of toward the wall.

In lighting the face care must be exercised about pointing the camera upward or downward; that is, having it too high or too low, as it will make a great difference in the modelling.

A high forehead may be lowered by depressing the head and so having more of the hair show. Should the subject have an upturned nose, the camera may either be raised or the head depressed.

If the camera is too high and the subject close by, the head will appear disproportionately large, the neck short, and the shoulders raised, and the subject will have the appearance of falling forward in the portrait: if too low, the head will appear too small and as if receding.

On account of the nearer position of the camera, a large head will require a longer exposure than a full length portrait.

Place the camera rather high when it is desired to avoid emphasising the nostrils. Persons with snub noses should not have the head directed upward, while those with long noses

should not have the head directed downward. A drooping nose should be taken with the head slightly thrown back.

By skilful lighting, irregular or crooked noses may be straightened in the portrait. They should usually be in shadow. A crooked nose is more noticeable on a full face portrait; its curvature should be turned toward rather than away from the lens if taken three-quarters.

A broad nose should not be taken full face nor a hooked nose in profile. A round or flat nose should usually be taken in profile or three-quarters, as may seem best. A bridge or bony nose should be taken three-quarter and in shadow.

A strong shadow on the face cast by the nose suggests a large nose; absence of shadow tends to soften the nose.

Avoid top lighting with an aquiline nose.

The shadow cast by the nose should never quite meet the shadow on the shaded side of the face. Some light should be reflected by the cheek to throw light on the shaded side of the face.

A wide mouth should not be taken full face. If the lips turn down, the poise of the head should not be such as to exaggerate them. A projecting chin or a protruding lip should not be taken in profile.

Side face poses are best when dealing with people with large mouths, prominent ears, eyes of different sizes, or eyebrows of different levels. Full face poses are best in cases of small mouths, receding foreheads, and occasionally of badly proportioned noses.

People who do not close the mouth should be allowed to hold the mouth naturally, but it should be placed in shadow. When the teeth show, they should also usually be placed in shadow.

Large ears should not be taken full face, and the side toward the camera should be in shadow.

A subject much freckled may be put slightly out of focus to minimise retouching.

When the camera is brought close up there is a tendency to narrow the face; when it is farther back the face will look broader.

If head-rests are used, first pose the sitter, then adjust the head-rest to the sitter and not the sitter to the head-rest. If the lens will work at large aperture and the light is good, it is better to avoid the use of head-rests altogether.

Sharp elbow angles are difficult to pose satisfactorily.

The operator should not move from his position when a settled pose has been determined upon and arranged and he is ready to make the exposure, as this may disturb the subject.

In profiles a little more space may be left in front of the face in focussing or in trimming.

Profiles do not give as characteristic a likeness unless the face is dominated by the nose or the chin rather than by the eyes and mouth.

A stooping figure should not have the body taken in profile.

Full face portraits tend to show up any serious lack of symmetry in the features.

The swing back may be used to get the knees in focus without using a smaller stop, provided the subject is not too close to the camera. The side swing may be used to get the near shoulder in focus in large figure studies.

If the subject is too self-conscious, it is often a good rule for the operator to make a pretended exposure, when the subject will probably relax and the shutter may be released. Always try to engage the sitter in some subject in which he is interested, so that he may forget himself. His characteristic poses and gestures may be best observed before he is placed in front of the camera.

J. W. LITTLE.

(To be continued.)

## IMPROVEMENTS IN PLAIN PAPER PRINTS.

[The following article from the "Bulletin of Photography" gives the formulæ advised by a modern worker for a process of printing which was, in fact, about the earliest precursor of the self-toning paper of to-day. A very similar method was published in "Wilson's Mosaics" for 1888, and was discussed in the "British Journal" for April 27, 1906.—Eds. "B.J."]

I HAVE always been an admirer of plain paper prints, especially for their artistic qualities and for the variety of beautiful tones possible. I have tried the formulæ of Doctors Mitchell, Miller, and others, published in the "Bulletin of Photography," and can attest to the trustworthiness of the plans they recommend. I recently tried some so-called self-toning paper, but at once discarded it, as I was not able to get any approximation to the fine effects with toned plain paper prints; however, it suggested to me a method which gave most delicate neutral tones, and in return for the many valuable hints and suggestions I have had from your publication I send you my method.

It occurred to me (probably the idea is not new) to use gold as a salting agent, instead of using it afterwards in the toning bath, thereby saving time.

I found that the English drawing papers worked more delicately than Rive's or Saxe's, Whatman's paper especially. The French and German papers gave greater contrasts but less delicacy of tone, and as the taste in photographic art nowadays is to less contrasty work, I think the English paper is preferable, especially as I employ a paper which will stand the action of boiling water.

The salting solution is made in the following manner:—

Chloride of gold .....	60 gr.
Chloride of ammonium .....	120 gr.
Water .....	30 oz.

Float the paper on this bath in the usual way, and allow it to remain on the surface until it begins to flatten out, which

depends upon the temperature of the room and also upon the character of the paper, from half a minute to a minute and a half.

It is then to be hung up in a warm place, but if near the fire have a care not to place it too close up. The object is to get it dried as quickly as possible. Do not have it too dry, but rather we should say merely surface dry. Mark the salted side with a cross.

The exciting solution is made as follows:—A sixty-grain solution of ammonia-nitrate of silver, made by dissolving 3 oz. of nitrate of silver in 16 oz. of water and then converting it into ammonia-nitrate of silver by the careful addition of strong ammonia until the precipitate first formed is redissolved, but only redissolved. Do not get excess of ammonia. Then add 4 oz. more water, making in all 20 oz. of solution. If ammonia is in excess the prints will be grey and weak; if it is deficient the proofs will be hard and bronzed.

Float the salted paper on this solution from a minute and a half to three minutes, according to the same conditions which influence the time on the first solution. The paper must now be thoroughly and quickly dried in a warm room or near the fire, observing the same precautions as with drying the salted paper. The paper will keep about a week in winter time, but I prefer making just the quantity needed for the occasion. It is better to have the fresh. The proofs should be slightly over printed.

My fixing solution is made as follows:—To 20 oz. of water

add 5 oz. of hypo and 14 grs. of iodide of silver. (Iodide of silver can be purchased, of course, but it is easily made by adding iodide of potassium to nitrate of silver.) When the above formed solution is complete, add 1 oz. of the ammonia nitrate solution used in sensitising. Keep this fixing bath for a few hours to ripen and preserve it for future use, as it works better after several proofs have passed through it—from absorption of the gold, doubtlessly. All that is required is to fill up the amount with fresh solution. It ought to smell quite strongly of ammonia; if not, add a very small quantity.

After printing, place the prints, without washing, directly in the fixing solution, where they should remain for an hour. Take out, draw off, and lay each print in a tray singly, and pour boiling water over it. Treat each print to the hot bath and transfer to a second dish of hot water until all are finished.

Let the accumulated prints in the second dish lie for five minutes, then drain off the water and pour more hot water on them. Finally, wash in the usual way for half an hour. Of course, the boiling water takes all the size out of the paper, and, as we said, you see the necessity of good stock. The proofs are very tender, and must be handled carefully in drying. The removal of the size contributes to the delicacy of the effect.

The French and German papers do not require so much gold in the salting; as much as one-half the quantity will suffice, but the effect produced is not as delicate. You may object to this process because it is not very economical, but I believe that mean savings have no consideration to those who desire fine results. And I will say that you will be satisfied with the beautiful artistic tone this method yields.

C. W. MACFARLANE.

## CARBON PRINTING ON IVORY BY SINGLE TRANSFER.

[The following alternative method of transferring the carbon Debenham, is one which, we believe, has been occasionally employed in practice. In the hands of skilled workers it is capable of excellent service, but owing to the absence of "tooth" from the surface of the ivory, there is a danger of the print splitting off after colouring, particularly if much gum be used in the latter process. The use of a substratum on the ivory, as described in our article of October 16, avoids this risk.—Eds. "B.J."]

The appearance of an article recently in the "British Journal of Photography" on "Photographs on Ivory" reminds me that, although I have given it to a few, I have never published a method which I worked out some years since, and which may perhaps prove as useful to some others as it has been to me.

An objection that I found amongst artists to colouring on ivories that had received a carbon image by double transfer, or a transferred collodion image, was that it was not an ivory surface that was given them to work upon, but the surface of whatever medium was used for making the transfer adhere. When working by single transfer the objection does not arise, as the carbon tissue adheres without substratum: but in the ordinary way, when printing by single transfer, the ivory becomes hopelessly stained by the bichromate solution used in sensitising. To get over this difficulty I employ the method as follows:—

The tissue is sensitised in a solution containing not more than 2 per cent. of bichromate of potash. I have found, by the way, that a weak solution answers better with me than a strong one for any ordinary carbon printing. About a fourth part of the solution is stood aside, and ammonia added to the remainder until the solution becomes very pale yellow, when the remaining fourth part is added to it. For drying the tissue I squeegee it on to talced glass, and leave it there until wanted. The surface, being out of contact with the air, will keep good and fresh longer than if exposed. There is also another advantage of drying on glass, as the paper retains its expanded condition, and so will not give the same slight amount of distortion—by expansion in one direction more than the other—which takes place when tissue is dried in the air, and then washed before being placed on its support for development.

### The Reversed Negative.

The negative, when, as is usual, a left to right inversion of the image would be an objection, must be specially made (except in the case of a film negative), but this is not a serious objection generally, as an ivory picture has commonly to be of a different size from the original photograph, so that a copy negative must be made anyhow, and, now that plates are sent

out without emulsion messes on the back, it is easy to make a reversed negative by exposing through the glass; laying a piece of black paper, and then any waste plate, upon it, to keep off contact with the spring of the dark-slide. With the diaphragm used for copying, the slight displacement of focus will not generally be noticeable, but if thought necessary to allow for this, the camera back may be shifted towards the lens about half the thickness of the plate in use.

### Preparing the Safe Edge.

As the tissue has to be developed upon the ivory itself, it must have a safe edge, leaving the image a little smaller than the ivory; and this is conveniently secured as follows:—Fold a piece of black paper over the edge of the negative, making a sharp crease both at the back and front of the glass. Now, on the flap which is to lie on the film side, cut a small hole opposite the head. As this hole enables one to see what one is doing, it may be enlarged with the scissors until it is of the size of the ivory, and has the head properly adjusted to that position it is to occupy. The flap of paper which is to go on the front of the glass has now to have a hole cut in it opposite to that which has been made in the film-side flap, but one-eighth of an inch smaller all round, and the corners may be slightly rounded off. There should now be no difficulty in replacing the double mask on the negative, with the larger opening next the film, and occupying its proper place with regard to the position of the image.

### Printing and Developing.

The tissue is cut the exact size of the ivory, and it is well to avoid going to the extreme edge of the tissue as sensitised (cut away, say, an eighth of an inch before cutting the piece to be printed), and laid in the space which has been cut out of the mask. For printing, an actinometer must, of course, be used. I use one which I described some years since in the "B. J. Almanac," but one on very similar principles is now commercially supplied by the Autotype Company. When printed, the tissue is thoroughly washed, to remove all the soluble bichromate before placing it in contact with the ivory. This may take from half an hour to an hour. Of course, in this soaked condition there would be no adhesion to

the ivory, but the surplus water is removed by immersion in alcohol—methylated spirits will serve—and two changes may be necessary. When the tissue is seen to become first flat, and then to have the edges turned a little inwards, instead of outwards, it is judged that the water is sufficiently extracted; and then, after pressing in blotting-paper, it is rapidly rinsed until the greasy-looking lines almost disappear, and then laid upon the ivory. It is quickly placed in a double flap of two or three thicknesses of blotting-paper, and then put under pressure in an ordinary printing-frame for about half an hour, when it is developed in warm water in the ordinary way. If desired to have some parts of the lights, as painters sometimes

prefer, quite free from image, they may be gone over with a little cotton wool under the water.

It might answer to dry the tissue after washing out the bichromate, instead of extracting the water with alcohol. I have not tried this, as time was generally important, but I see no reason why it should not succeed.

It is, of course, quite possible that others may have worked out a similar process, and it may even have been published; but if so I am not aware of it, and anyhow, it is not so generally known that the present publication may not be of interest to some workers.

W. E. DEBENHAM.

## PHOTOGRAPHY IN THE STUDY OF THE STRUCTURE OF METAL SPECIMENS.

(From the "Scientific American.")

IN recent years an entirely new branch of practical science has grown up, to which the name of metallography has been given. A metallograph is a pictorial representation disclosing the structure of a metal specimen. It has long been known that much might be learned of the characteristics of, say, a piece of steel by the mere optical examination of the structure disclosed by a fracture. The difference in appearance of a fresh fracture of hardened and tempered razor steel from a fracture of, say, cast iron, is quite apparent to the eye. But in order to study this line of things with effectiveness, some means of recording these appearances was necessary. This has been filled by photography. An unmagnified representation—made by photography or otherwise—of a metallic fracture is called a macrograph. For the production of macrographs a vertical arrangement is especially desirable, as thus the sunlight may readily illumine the surface of a fracture. This specimen is placed, fracture side up, upon the table. The whole camera may be adjusted vertically along the post, rising from the post by means of a locking arrangement. The focusing is accomplished in connection with the rod on the upper right hand.

However, while the study of macrographs is no doubt of considerable importance, the present state of the study of metallic structures would have been hardly possible of attainment through them alone. The microscope has been brought into this line of research, and with the most important results. A magnified representation of a metallic fracture is called a micrograph.

Now it might seem to some that, with chemical analysis on one hand, and mechanical testing on the other, there would be little that could not be learned about metals by means of one or the other of these processes. That this is not the case may be seen from the fact that metallography is making a place for itself by the intrinsic value and uniqueness of its information. The chemist could tell us, no doubt, that a given specimen of steel contained just so much iron, so much carbon, so much silicon, and so on to the last minute impurity. The mechanical tester could inform us as to its capability of withstanding compression, of its resistance to tension, of its degree of hardness, and so on. Now if our piece of steel were an absolutely homogeneous, non-crystalline substance, the metallographist would probably have nothing to add. But steel and many other metals have a definite structure. In fact, the micrographs show that it is a most complex substance—not complex merely from the fact that it contains quite a number of different substances, but because it is an aggregation of substances which differ from each other in form and characteristics. In other words, steel is not a perfect chemical compound. Metallography not only informs us of this fact, but instructs us as to the form of the structure.

It is found, particularly with steels, that the structure varies with the heat treatment to which the specimen may have been subjected, with its chemical constitution, and with the mechanical operations which it has undergone. Thus the percentage of carbon influences the structure. A great variety of structural changes is brought about by heating, chilling, over-heating, and the like. Cast steel, steel hot forged under the hammer, and steel cold rolled, all differ in structure. The expert metallographist is able, in fact, to discern from

his metallographs a good deal as to what has happened to the steel under inspection.

Now it is not quite so easy a matter to make a micrograph as it is to make a macrograph. It is necessary to prepare the specimen for microscopic inspection; and it must be flat and highly polished as a preliminary to the final processes.

There are four methods of preparing the test piece. (1) It may be etched with acids and the like; (2) it may be polished in bas-relief; (3) it may be polished by "polish attack"; or (4) it may be tinted by heating.

To etch the surface, nitric acid, iodine, or picric acid may be used. The object is to affect differently the different substances making up the complex structure exposed by the fracture, with a view of creating different optical conditions, so that when exposed to a strong light the etched surface will disclose in the microphotograph light and dark effects corresponding to the structure. Ordinarily, the surface should be carefully polished before etching.

Polishing in bas-reliefs depends for its success upon differences in hardness of the different parts of the complex. Upon treating the specimen to a series of polishing operations—proceeding from a rough polishing with files to that obtainable with emery papers and rouge—it is possible to produce a surface free even from microscopic scratches, which will yet be unequally worn in detail although flat as a whole. This is considered a very fine method—especially applicable to certain cases. Thus, Professor Stoughton points out that this method is particularly advantageous in differentiating the graphite in pig iron, as it does not produce the discolorations to which an acid etching might give rise. In preparing his own specimens, he performs all the polishing operations, except that with the rouge, by hand. There are, however, one or more varieties of apparatus for accomplishing this by mechanical means.

The method of preparation called "polish attack," as used by F. Osmond, of Paris, consists in performing polishing operations by means of parchment which has been treated with a little ammonium nitrate in solution. This method is a finishing operation, and is performed after coarser means of polishing have been used.

The process of tinting by heat depends upon the fact that, upon application of warmth, the different constituents of the polished surface will oxidise differently, thus producing differentiating effects discernible by the photographic plate.

F. Osmond, of Paris, is one of the leading metallographers. He recommends the application of a series of finishing operations. Thus, after the preliminary preparation of the specimen, it may be treated to polishing in the bas-relief, then to "polish attack," and finally to the action of chemicals. Photomicrographs may be made after each stage.

However, whatever process or combination of processes is employed, the problem of preserving a record is solved by the use of a magnifying apparatus in combination with a photographic camera.

It seems to have been pretty well ascertained that the finest grain of pure carbon steels is developed at about the temperature of 1,300 deg. F. As this temperature is exceeded the size of the grain continually increases, and apparently with great regularity. If the

steel has been overheated, and has consequently developed a large grain, this serious fault may usually be corrected by cooling below the temperature just mentioned and then reheating to some point above it. When the heat of 1,300 deg. F. is just reached, the fine grain begins to form. If the steel has a carbon percentage of precisely 0.9, a few degrees in excess will be sufficient ordinarily to cure the large-grained structure. But if the carbon is much below 0.9 then the reheating will have to go considerably beyond, 0.4 carbon requiring a temperature of about 1,470 deg. F. If the carbon percentage is quite low it may be necessary to heat to 1,600 deg. F., or somewhat beyond. The reason for heating beyond 1,300 deg. F. is that steels having less than 0.9 carbon are composite in their structure, and reheating to 1,300 deg. F. does not uniformly affect the whole mass. The old grain size (developed by the over-heating) tends to persist. If the steel has more than 0.9 carbon, the necessity for heating above about 1,300 deg. F. to effect restoration is not pressing—the imperfection from want of uniformity being but slight. It is evident that the new science of metallography is eminently adapted for investigation into this whole matter of size of grain.

J. F. SPRINGER.

#### THE BLACKPOOL PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

A meeting of Blackpool professional photographers, held in the King Edward VII. Hotel, on Friday, November 13, it was unanimously resolved to form an association, to be called the Blackpool Professional Association, its object being to protect the profession against itinerants who flock into the town in the summer months, and who, without sharing in the expenses of the town, reap all the benefit to be had in the busy season and then clear out, thus doing great injustice to all the photographers who are paying rates and taxes in the borough of Blackpool.

The subscription was fixed at the nominal sum of 2s. 6d. per annum, and all members to join the Blackpool Tradesmen's Association, the subscription for the latter 5s. per annum extra.

The following gentlemen enrolled themselves as members and paid their subscriptions:—

Bland Wolfenden.  
C. F. Wiggins.  
H. Wiggins.  
H. and W. Cooper Bros.  
S. Wolstenholme.  
J. P. Bamber.  
W. J. Gregson and Tansey.  
Smith and Whittaker.  
E. E. Hindley.  
J. Watson.  
J. Eastwood.

Mr. Bland Wolfenden was unanimously elected as president, and Mr. C. F. Wiggins as vice-president.

Mr. H. Cooper as hon. treasurer.

Mr. H. Wiggins as hon. secretary.

A committee was also formed of the following gentlemen:—J. Smith, E. E. Hindley, J. B. Bamber, J. W. Gregson, Ellis Wolstenholme, W. Buckley.

#### FORTHCOMING EXHIBITIONS.

December 9 to 12.—Bolton Amateur Photographic Society. Secs., A. N. H. Wyde and J. Bailey, 25, Croston Street, Bolton.

December 30 to January 2.—Chelmsford Photographic Society. Entries close December 17. Sec., M. J. Morison, Savernake Lodge, Chelmsford.

December, 1908, to January, 1909.—Kiew International Photographic. Sec., S. T. Horowitz, Technical Society, Kreshtchatik, 10, Kiew, Russia.

1909.

January 1 to 9.—Scottish National Photographic Salon. Entries close December 7. Sec., Robert Telfer, 138, Glasgow Road, Wishaw.

January 6 to 27.—Northern Photographic (Manchester). Entries close December 11, 1908. Sec., S. L. Coulthurst, Broad Oak Road, Worsley, Manchester.

February 13 to March 15.—South London Photographic Society. Sec., H. Creighton Beckett, 44, Edith Road, Peckham, S.E.

## Photo-Mechanical Notes.

### Half-tone Blocks Direct in the Camera.

According to the description given by Max Ullmann, of 16, Thalstrasse, Zwickau, Germany, the following process is used for the preparation of half-tone or line blocks by exposure of the printing plate in the camera in the first instance. The process is the subject of a patent (No. 21,481, 1907).

The invention relates to a process for producing printing blocks for line drawings "half-tone," and other half-tone pictures decomposed into lines or points after the style of line drawings, in which process the production is effected by direct exposure in the photographic camera, namely, by photographing the object by means of lens and camera direct on the printing plate, which has been coated with a sensitive film of the composition given below. The plate after exposure is developed in the known manner and then serves as printing block. The metal printing plates are thinly coated with a mixture of previously liquefied gelatine and bichromate of ammonium (with ammonia added), which is allowed to harden or set. After exposure the plate is developed in a bath consisting of nitric acid (4 per cent.) and is then ready for use as a printing block.

The usual method is now followed—i.e., the plate is dried, has transfer colouring medium rolled on to it and is then washed. The places affected by the light do not take the colouring medium, while the latter adheres to the places that were not affected by the light, so that the plates can be printed from direct.

The inventor states that the separate working stages in the preparation of the printing plate as above set forth are known *per se*; and the invention consists in combining them in the manner herein stated with a view to obtaining a specially good result. The process of the present invention has the advantage that the metal plates are at least as easy to handle as glass plates and that they are adapted to print from direct—i.e., without a previous transfer stage.

If the printing plate is to be used for lithographic printing, it can be made use of without further treatment. If it is to be used for book printing it has to be etched in the known manner after the application of the colouring medium.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for Patents have been received between November 9 and November 14.

**MOUNTS.**—No. 23,977. Improvements in frames and mounts for photographs and the like. Gerald Robinson and Herbert Willand Robinson, 128, Colmore Row, Birmingham.

**FILMS.**—No. 24,066. Improved device for securing and linking-up photographic films, papers and the like to and upon frames, spools or supports. Harrison Ward, 22a, Duntshill Road, Earlsfield, Surrey.

**DEVELOPMENT.**—No. 24,429. Improved developing dish for negatives and flat films. Charles Noel Wedlake, 147, Clapham Road, Surrey.

### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

**MOUNTING P.O.P. PRINTS.**—No. 23,762. 1907. The invention relates to a process for mounting gelatine emulsion photographic paper, prints, and its object is to preserve the lustre and also save the expense and inconvenience of card mounts. The superior tone of collodion or platinotypes papers is obtained.

After the prints have been completed glass plates are prepared to receive them and cleansed thoroughly, care being taken, of course, to observe that there are no flaws in the plates. Each print is then taken singly and dipped in clean water at a temperature of about 70 deg., and is then laid on the glass plate. After the print has been applied to the glass plate it is subjected

to pressure or a squeegee operation by means of a suitable implement which may be made of any suitable material, such as rubber or celluloid, and of a convenient form or shape to adapt it to squeegee out all the water and also the air between the print and the glass plate, and when this latter operation of removing the water and air has been completed, the glass plate with the print thereon is placed to one side and permitted to dry.

If the foregoing process is fully carried out, the result will be a picture having a tone similar to that printed out on collodion or platinotype paper with the advantage of adherence to the glass plate.

The inventor states that he is aware that it has been proposed to mount photographic prints on glass by slightly warming the glass, putting some warm melted gelatine on it with a brush, placing the print on the glass face downwards, rubbing and pressing it with any suitable tool until air bubbles and marks have disappeared, and allowing it to remain until dry. Harry Schmidt, 406, Broadway, Council Bluffs, Pottawattamie, Iowa, U.S.A.

**DARK ROOM LAMPS.**—No. 12,649. 1908. This invention relates to photographic dark room lamps and to that class of lamp in which two chambers or compartments arranged in juxtaposition to each other are provided with a lamp or candle capable of being moved from one compartment to another for the purpose of limiting the

rays of light to escape through either of the glasses of the compartments one at a time, the glasses being of different colour, such as red and yellow, for the purposes well known in photography. The invention consists of an improved form of lamp having the advantages of compactness, ease of manipulation, good appearance and simple construction.

In constructing the lamp two glass cylinders are arranged one above the other, the lower one being fitted into a base and the upper one closed by a cap having fitted to it a rod capable of being slid backwards and forwards through the cap and held at any required position therein, the rod supporting an electric or other light and being provided with a screen which can be used to confine the light to the lower of the two chambers.

The two glass cylinders are held together by an external band as by providing it with an inside thread which will fit an external thread on the two ends of the cylinders.

It will be seen from the drawing that the case of the lamp consists of two principal parts A and B which are formed from glass cylinders, A being of yellow colour and B red. The cylinder is fitted into the base D and has bottom plate E and light-proof cap F, the base being furnished with air holes and the cylinder A is provided with a cap J also furnished with air holes and having a hole through which the rod C is fitted and in which it can slide, the rod carrying the lamp L and shade S.

A ring is fitted around both the adjoining ends of the two cylinders and serves to hold the same together, a darkening ring T being also provided to ensure the light being entirely cut off from the upper chamber of the lamp when in lowered position as shown in dotted lines.

As the lower cylinder is of red glass it is immaterial when the lamp is raised whether the light shines through it as well as through the upper yellow glass. Max Muthel, 69, Faubourg Saint Martin, Paris.

**PHOTOGRAPHIC FILMS.**—No. 8,875. 1908. The subject of the invention is an improved flexible plate, or film, for photographic purposes, which in addition to being exceedingly durable and cheap to manufacture, is of such nature that the shadows cast in printing by the grain or structure of the material employed as support for the sensitive medium are caused to vanish, owing to dispersion of the light.

A basis of paper, fabric, or other suitable material is used. To this support is applied an "optically glassy" layer consisting of a mass of dextrine, or some kind of glue, resin, varnish, or other similarly diaphanous substance. This "hyaline" layer serves to disperse the light in printing out, and in order that the shadows due to the texture or grain of the support may be effectually diffused, it is found that the layer should be of at least the same thickness as the base which supports it. The sensitive material is distributed over the intermediate glassy layer.

By means of the invention the disadvantages attending the use of paper or like films, owing to the shadows arising in printing, are thus entirely obviated. At the same time the negatives given are free from halation. Max Hansen, 217, rue St. Honoré, Paris.

**CINEMATOGRAPH MECHANISM.**—No. 24,157. 1907. The invention relates to cinematograph projectors or cameras, wherein the film is fed past a mask or aperture through which the light passes, and to that kind wherein the film is kept frictionally tight by variable spring pressure, the object of the invention being to improve this class of device by rendering it more durable and effective than heretofore. A hinged door has two longitudinal grooves in which two bars lie. The bars, hereinafter termed "pressure bars," are kept in position by means of two or more screws on the ends. In the grooves four holes are provided. On the outer side of the doors are two crossbars, each provided with two pins which project through each pair of holes, and press upon the two pressure bars through the medium of a centrally mounted spring which is adjustable by means of a screw and nut. The framework of which the door is hinged is also grooved out. In the groove a bar with a mask the same size as a picture is laid, which is kept in position by means of a screw and it made removable for convenience of cleaning. Leo Kamm, 27, Powell Street, Goswell Road, London, E.C.

## New Trade Names.

**ENSYNODS.**—No. 304,684. Chemicals used in photography. Houghton & Co. Ltd., 88 and 89, High Holborn, London, W.C., manufacturers of and dealers in photographic, optical and scientific apparatus. July 14, 1908.

**HAKO.**—No. 306,241. Chemical substances used in photography but not including enamels in the nature of paint and varnish included in this class, and not including any goods of a like kind to any of these excluded goods. Chemische Fabrik auf Actien (vorm. E. Schering), 170, Müllerstrasse, Berlin, Germany, manufacturers. September 16, 1908.

**SATRALBIN.**—No. 306,243. Chemical substances used in photography. Chemische Fabrik auf Actien (vorm. E. Schering), 170,

Müllerstrasse, Berlin, Germany, manufacturers. September 16, 1908.

WYNA.—No. 304,686. Photographic papers. Houghtons Ltd., 88 and 89, High Holborn, London, W.C., manufacturers of and dealers in photographic, optical and scientific apparatus. July 14, 1908.

AKO.—No. 306,242. Photographic paper. Chemische Fabrik auf Actien (vorm. E. Schering), 170, Müllerstrasse, Berlin, Germany, manufacturers. September 16, 1908.

WALBIN.—No. 306,244. Photographic paper. Chemische Fabrik auf Actien (vorm. E. Schering), 170, Müllerstrasse, Berlin, Germany, manufacturers. September 16, 1908.

## Analecta.

*Extracts from our weekly and monthly contemporaries.*

### Improved "Blue" Printing.

My own method of working this process (writes Mr. Leslie Truss in *The Amateur Photographer and Photographic News*) for November 1908, as described below, while embracing far more time and trouble, yet so vastly superior to the usual way in results, if not in rapidity, that I have stuck to it firmly. The method of procedure is as follows:—The negative print (i.e., undeveloped), which should be slightly darker than is usually necessary, on being removed from the bath must be first bleached for about five minutes in the following:—

Water .....	8 oz.
Liquid ammonia .....	40 minims.

The ammonia should be added just previous to use and after immersion. The print will be found to be a pale grey positive; this should be well washed for another five minutes in running water and then developed in

Citric acid .....	200 grs.
Water .....	8 oz.

Development will be almost instantaneous, the colour being a decided green at first, and the blue print fully developed in about half a minute, after which ten minutes' washing should ensue. I attempted to stop development while the colour was in the green stage, but the extreme rapidity of action in the acid bath entirely prevented this. The finished print will be found to be quite equal in brilliancy to O.P., the high lights being clear and unstained, and detail showing well up in the half-tones. In conclusion, I may state that either citric acid or acetic, in concentrated solution, may be used in place of citric acid, but I have found that the latter gives the most brilliant results and is altogether the cleanest working bath of the three.

### Splitting a Sheet of Paper.

Mr. W. E. Hickling, writing in "*Photography and Focus*" for November 24 on copying by contact from both sides of a sheet of printed matter, describes a method by which the paper may be split in two, thus leaving the printed matter on one side only. "Two pieces of smooth strong calico are procured, each a little larger than the paper to be operated upon, and also some good strong glue, care being taken to ensure that it is evenly covered, particularly that no portion of the surface is left uncovered. Then immediately, before the glue sets, one piece of the calico is laid on the glued surface of the paper and pressed down into close contact with the paper in every part. The other piece of paper and calico are then turned over, and the other side of the paper is coated in the same manner with the glue. The other sheet of calico is then applied to it in exactly the same manner. The whole sheet of paper and two sheets of calico is now left to set and dry under slight pressure. When it is thoroughly dry the two pieces of calico are pulled apart evenly, and if the operation has been carefully performed, one half of the paper will remain attached to each of the two pieces of calico. It now only remains to soak off the paper from the calico in tepid water and to dry them. The surface of the paper is improved by being ironed with a warm iron (not hot enough to scorch the paper)."

## New Books.

"Life Histories of Familiar Plants." By John L. Ward. London: Cassell and Co., Ltd. 6s.

A most entertaining book this, of the development and habits of plants. The author's aim is to interest lay readers in the scientific study of plant life, and this he has certainly attained in a way which cannot fail to attract the amateur student of nature without wearying with strings of Latin names; the chapters contrive to impart a great deal of real instruction in the processes upon which depend the characteristics and properties of our familiar flowers. The author's photographs and photo-micrographs do him credit, both as an illustrator and photographer, and we can commend the volume as a gift-book of natural history, which owes its interest to the writer's sense of humour and to his appreciation of the difficulty of the non-botanical person.

"La Photographie." By G. Chicandard. Paris: O. Doin et Fils. Five francs.

This book is quite distinct among both French and English textbooks of photography. It is indeed not an instruction manual, but a précis of photographic processes past and present, with particulars as to date and author in almost every case, all very carefully arranged according to the Dewey decimal classification. This general review of photography past and present is to be amplified in necessary directions by the publication of other volumes uniform with the one before us, and dealing in the same systematic way with special sectional treatises. Among the subjects announced to be dealt with this way are: Negative making, positive printing, colour photography, photography by artificial light, micro- and macro-photography, stereoscopic photography, and photo-mechanical reproduction processes. We do not know whether in each of these cases the volume will partake of an historical character, but the arrangement of the book now before us can hardly be improved upon. It conveys a very large amount of information, tersely expressed, though it is not to be recommended to the reader unable to distinguish from the current and the obsolete.

## New Apparatus, &c.

The Zeiss Tele-Camera. Made by Carl Zeiss, Jena, and 29, Margaret Street, London, W.

This camera is an instrument specially made for natural history, landscape, and portrait work, and permits of advantage being taken of the new Zeiss telephoto lens. The camera consists of a metal leather-covered case measuring  $8\frac{1}{2} \times 5 \times 6$  inches, and fitted with the "Palmos" focal-plane shutter. The lens is mounted on a tube about 9½ inches in length in such a way that excepting the portion carrying the iris diaphragm and the adjustment for objects at various distances the tube pushes inside the camera leaving a projecting portion only

2 inches deep. This adjustment is very rapidly made simply by raising the spring catch and then turning the clamp seen in the illustration. The weight is thus very nicely distributed for carrying, whilst the bushes, serving to fix the camera to a tripod, are placed right in the front, so that the weight is again fairly equally distributed when the camera is in use. The production of a telephoto lens at the large working aperture of  $f/10$  and a focal length of 32 inches is surely a triumph, when it is considered that the distance from lens-hood to plate is only 17 inches, whilst with the camera closed this is reduced to 10½ inches. The camera is naturally

weighty, but for special long-distance work of all kinds is a remarkably fine instrument. The adjustment for focussing on distant objects provides a range from infinity to 5 yards, but while the image can be

focussed on the ground glass there is also provided a binocular field glass of four magnifications which serves as a finder. The price of the camera complete with lens, shutter, and finder is £40.

Lantern-slides of Famous Pictures of the World. Sold by W. Butcher and Sons, Camera House, Farringdon Avenue, London, E.C.

In this series of coloured slides Messrs. Butcher have provided at a most popular price reproductions of the most notable masterpieces of classical painters. The set includes altogether eighty different

subjects selected to represent the great schools and periods of painting. The lantern slide, from its nature, cannot render the characteristic appearance of many paintings, but the general results obtained by the lithographic process of reproduction are for the most part of a kind to give a good general idea of the various paintings, and to encourage the study of the many manuals on art. The choice of subjects, it should be said, is one which renders the slides suitable for any audience. The complete 80 slides are issued at the price

of 40s., inclusive of lecture and an excellent polished mahogany box for transit. Sets of eight slides are likewise supplied at the price of 4s

## New Materials, &c.

"Teb" Christmas Mounts. Sold by W. Butcher and Sons, Camera House, Farringdon Avenue, London, E.C.

That Messrs. Butcher have both recognised and appreciated the ever-increasing demand of photographers for Christmas mounts of dainty colouring, with simple lettering and design, is evidenced by an inspection of this new series recently placed by them on the

market. The cards are two-fold, of both the paste-on and slip varieties, and can be obtained with openings to take pictures of a size and shape, from quarter-plate to midget, at prices varying from 12s. to 24s. per gross; also in boxes containing 15, 12, or 10 assortments of the midget, carte-de-visite, and quarter-plate sizes respectively. Any of these cards can also be supplied as private greeting cards, the greeting being printed on a white inset leaf at a small extra charge, which varies according to whether the lettering is black or gold.

We would also draw special attention to the "Linette" series of calendars, which Messrs. Butcher are this year placing on the market, in addition to the well-known "Primus" calendars. The

former are made with stiff back and loose, apron-like front, containing a cut-out opening, this form having the obvious advantage that the photographer is enabled to mount his prints perfectly flat, a task which presents considerable difficulty with the usual slip-style of calendar. These "Linette" calendars are made in six varieties, and three sizes to take pictures 3 x 2, quarter-plate (upright) and quarter-plate circle, the price of all three being 24s. per gross.

### CATALOGUES AND TRADE NOTICES.

SECONDHAND APPARATUS.—The November-December bargain list of the City Sale and Exchange reaches us from 54, Lime Street, London, E.C. It is a large 16-page list, describing chiefly hand and field cameras and enlarging and projection lanterns. The list is sent free on application.

# Meetings of Societies.

## MEETINGS OF SOCIETIES FOR NEXT WEEK.

SATURDAY, NOVEMBER 28.

Camera Club. "A.P." Prize Slides.

MONDAY, NOVEMBER 30.

Photographic Society. "On the Printing, Developing, and Toning of Velox Papers." W. F. Slater.  
 Photographic Society. Five-minute Papers by Members.  
 and District Photographic Society. "The Photographic Lens." C. P. Goerz.  
 London Photographic Society. "Trimming and Mounting." W. Llewellyn White.  
 Camera Club. "The Carbon Process." A. E. Henley.  
 and District Photographic Society. C. P. Goerz Co.'s Prize Slides.

TUESDAY, DECEMBER 1.

Photographic Society. The Annual Dinner.  
 Birmingham Photographic Society. Midland Photographic Federation, Circulating Portfolio.  
 Photographic Society. "Natural History Photography." Riley Fortune.  
 Camera Club. Exhibition of Thornton-Pickard Prize Slides and Apparatus. R. Heskech.  
 and District Camera Club. Lecture for Beginners. W. Duxbury.  
 Camera Club. "A Few Old Sussex Churches." John King.  
 Camera Club. "Lantern Slide Making." J. Woodger.  
 Photographic Society. "Mounting." A. J. Linford.  
 Amateur Photographic Society. "On the Printing, Developing, and Toning of Velox Papers." W. F. Slater.

WEDNESDAY, DECEMBER 2.

Birmingham Photographic Society. "Photography as a Help to the Study of Ornithology." Rev. H. N. Bonar.  
 Camera Club. "Oil and Gum." A. W. Hill.  
 and District Photographic Society. Members' Slides.  
 Suburban Photographic Society. "Some Ancient Churches of Essex." C. Forbes.  
 Camera Club. Lantern Evening.  
 Polytechnic Photographic Society. "Various Novel Lighting Effects." H. Essenhigh Corke.  
 Camera Club. "Real Orthochromatism." S. E. Bottomley.  
 Photographic Society. "On the Printing, Developing, and Toning of Velox Papers." W. F. Slater.

THURSDAY, DECEMBER 3.

Photographic Society, Y.M.C.A. "Bromide Toning." T. Hartley.  
 Camera Club. Members' Lantern Slides.  
 Amateur Photographic Association. "On the Printing, Developing, and Toning of Velox Papers." W. F. Slater.  
 Photographic Association. "Composition and Selection." J. Campbell.  
 and District Camera Club. "Afar in the Fatherland." W. L. F. Wastell.

## ROYAL PHOTOGRAPHIC SOCIETY.

Meeting held November 24. Mr. W. Bickerton lectured upon "Wild Birds and their Ways," illustrating an interesting discourse upon a few of the less common British birds with a series of 120 lantern slide photographs. Mr. Bickerton explained that his natural history photography was done in the few leisure hours allowed by his business pursuits. As shown by the large number of photographs of a very small number of birds, his aim had been recording the habits of his subjects in a good many aspects, and in this way he was able to keep his audience interested in the characteristic doings of some of the less familiar wild birds.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION. — At the meeting held on Thursday, November 19, the Rev. F. C. Lambert presiding in the chair, Mr. Ernest Marriage gave a lecture upon "Telephotography." He said that many thought that the telephoto lens was only useful for distant views, but in practice it would be found that it was a most useful instrument to have for near objects, as for instance the taking of water plants, where one would in the ordinary way have to put up with them being either of a small nature or the other hand have to wade up to the knees to get the view that was wanted. To take a small part of a negative taken with the ordinary lens and to enlarge it did not give the same effective picture as did the telephoto negative taken direct, owing to the large falling in sharpness in the enlargement, which would be rendered crisp and sharp in the direct print. A large aperture lens should be used with the negative lens if at all possible, owing to the lengthened exposure required when doing telephoto work. With a good telephoto attachment the amount of magnification could be varied at the will of the user, and thus varying effects could be obtained. A point to be remembered was that the camera intended for use with the telephoto lens should be fitted with a larger amount of swing to the

back than was usually fitted, owing to the fact that it was often desirable to take in parts of a building that were high up, and without the great amount of swing it would not be possible to get the lines true. At the same time he found that the old rule of keeping the back perpendicular did not hold good for telephoto work, as it was often the case that when the back was so used that the lines would be out of truth, the only way was to examine the image on the screen and to swing the back until one got what was wanted. Caution should be exercised when calculating the exposures, as to the scale marked upon the sliding tube of the lens. These were supposed to give the magnifications, but were a delusion and a snare; they could only be right for one point, or distance, and should therefore not be taken any notice of. An easy way of calculating the exposure, the lecturer said, was to first find the magnification, by dividing the distance from the negative lens to the focussing screen by the focal length of the negative lens used, and then add 1 to the result. This would give the magnification. To find the F value or intensity of the lens, multiply the stop in the positive lens by the magnification, when one would get the F value of the lens complete.

SOUTH SUBURBAN CAMERA CLUB.—Meeting held November 18. Mr. J. Cyril Crowley lectured on "The Haunts, Habits, and Homes of a Few Wild Birds." Mr. Crowley showed a fine set of over 100 slides of birds and their nests, from the robin of the towns to the rare feathered frequenters of the Western Hebrides. To get some of these photographs he had to be temporarily marooned on a desert isle, where he built the hut that sheltered him from the inquisitive gaze of his unconscious siter. Others were secured while dangling on a rope from a precipitous cliff. One or two were taken by walking up to where the bird lay low, afraid to move lest her nest should be discovered; and in one case, a perch was provided in a prominent place, on which the perky little model posed of her own accord. A hearty vote of thanks was accorded to the lecturer at the close of an interesting evening.

BIRMINGHAM PHOTOGRAPHIC SOCIETY.—Mr. E. G. Collins lectured "On Making Photographic Christmas Cards." Photographic Christmas cards can roughly be divided into two classes. First, the simple mounting of suitable prints on a tinted paper or cardboard support, and then printing or writing the greeting by hand. Second, including all those cards which are entirely photographic, consisting of a photograph of a design or a combination of photograph and greeting. To the artistic photographer especially this opens out a field of work the possibilities of which are unlimited. Once a satisfactory design is obtained we have only to make a negative and print off the number required by any process. In making the negative a great saving of time is effected by making a rough copying stand with runners, on which an easel or support for the design moves to and from the camera, which is fixed. It is important to notice that the lines are kept absolutely true and square, and the design should be ruled off to a size bearing a relative proportion to the size of printing paper to be used. Having focussed the design at full aperture it is better to stop down a little, to secure better definition all over. As regards the plate to be used, the best is one of medium speed or an iso, and it should be backed to get the line work clear. Develop with a developer giving good density—e.g., hydroquinone or pyro-soda. If full density is not obtained you will have to mask the edges of the negative while printing to secure a clean print. Printing is best done on thick, ordinary, or cream bromide, or on a gaslight paper. Of the latter class "Gravura" is very suitable, as you have the power to alter the tone of the print. With normal development it gives a pure black, but by varying the developer and exposure tones can be got from sepia to red chalk. Dekko matte antique is a pleasing tinted gaslight paper, of heavy substance, suitable for cards.

If a folded card is desired, the smallest camera that can be used with success is half-plate. It can, however, be done without by making two quarter-plate negatives, one for picture and one for greeting. Care will have to be taken to mask the junction of the two while printing. For printing the greeting on cards of the first class, if the tinted mount is of a lighter colour, we may use ordinary or Indian ink, or if a softer effect is needed, Prout's brown. For all dark mounts nothing is better than Chinese white. It is mixed with water to a fairly thick consistence, and put on with a soft easy-running pen. A quarter-plate negative may be printed on to a half-plate paper by masking the whole of the paper, except where the print is to be. The greeting may then be written with ink in the usual way.

## Commercial & Legal Intelligence.

**A NORWICH BANKRUPTCY.**—The affairs of Edgar Wilkinson, residing at 218, College Road, Eaton, Norwich, and carrying on business at 1, The Arcade, Norwich, came before the Norwich Bankruptcy Court last week. The statement of affairs showed gross liabilities £1,092 16s. 3d., expected to rank £473 9s. 4d., deficiency £84 8s. 4d. In reply to the Official Receiver, debtor said he had been trading as a photographer at the Arcade. Some years ago he was assistant at Cambridge, and 22 years ago he started at that place with another assistant named Scott. He put about £150 into the business. The partnership was dissolved three years later, and debtor drew out £200. The dissolution was not gazetted. Leaving Cambridge he went to Higher Broughton, where he joined his brother, also a photographer. His father had left him some money, and he put £400 into the new business. The partnership lasted for six years, and debtor was paid out. He took less to go out than he paid to go in. The dissolution was not gazetted. Through an advertisement he bought the business of Mr. Howard Heath, of Rampant Horse Street, Norwich, for £200. He then possessed £300 and his furniture. That was in 1894. He traded at Rampant Horse Street until 1902, and was fairly successful. In June, 1902, he moved to the Arcade, at a rent of £266. He sublet a portion for £60, so his rent stood at £206. He moved with the idea of extending his business, but the move had not answered his expectations. He had never taken stock, and had kept no proper books of account for the last seven years. Since 1902 the competition had been very severe, cheap photographers had come into the city, and chemists had supplied photographic materials. He first became aware of his insolvency by reason of the pressure of his creditors. But for the difficulties raised by the owners of the Arcade he could have disposed of the remainder of his lease to advantage. Had he carried this through he would have met all his creditors. That was his last hope, and when it fell through he filed his petition. Whatever loss there had been had arisen in his business. He had not neglected his business, but had given it the whole of his attention night and day. The examination was closed.

**A MANCHESTER BANKRUPTCY.**—Max Muenzer, lately residing in Moss Lane East, Manchester, was examined at the Manchester Bankruptcy Court, last week, before Mr. Registrar Atkinson. Debtor was described as now managing director of a limited company, but lately carrying on business as a manufacturer of photographic materials and picture-frame maker at the Helios Photographic Works, Chester Road, and also as a photographic artist and enlarger, under the style of the Great Britain Art Company at Grosvenor Street, Manchester; and also at Newcastle-on-Tyne, Sunderland, Stockton, Hull, Leeds, Wolverhampton, Birmingham, Liverpool and Bradford. He submitted a statement of affairs which showed that he estimated his liabilities expected to rank for dividend at £4,190. As his assets he gave: "Sale price of business to Muenzer, Limited, cash payable before January 24, 1909, £4,000; 12,500 ordinary and 2,500 preference shares of £1 each, allotted as fully paid, £1,000," thus showing a surplus of £809. In answer to the Official Receiver, debtor said he commenced business as a photographic enlarger in Hyde Road, Ardwick, five years ago with £10 capital. Subsequently he took the premises in Grosvenor Street and Chester Road, the latter being his works. The business was prosperous, and grew rapidly. At the beginning of the present year he had assets amounting to something like £6,000. A company called "Muenzer, Limited," was formed to acquire the business, with a nominal capital of £25,000, divided equally into preference and ordinary shares. The shares were allotted, but no cash was paid, although he was to have had £4,000, in addition to the ordinary and preference shares, as set out in his statement. Practically, the Official Receiver said, debtor sold his business on credit—on a six months' bill. You got a piece of paper, which may be very valuable or very valueless, Mr. Gibson added, and to-day you have not got a shilling to pay your unsecured creditors? Debtor: No, I haven't, but what is due to me from the business. At present you have nothing? No. And your creditors' debts amount to something

over £4,000. Yes. The Registrar: At present it looks very much like a rather bad form of a one-man company. The examination was adjourned until January 22.

## Correspondence.

- \**Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*
- \**We do not undertake responsibility for the opinions expressed by our correspondents.*

### THE "THAMES" ONE-EXPOSURE COLOUR PLATE.

To the Editors.

Gentlemen,—May we be permitted to make one correction in Mr. H. Essenhigh Corke's very able and fair criticism of our plate? Treating the wider interstice between the red and green circles for the purpose of counting as a circle it will be found that the number of colour patches is 67,500 to the square inch—i.e., imperceptible as patches

the unaided human eye at a distance of six inches. As your next issue is a colour supplement, we should be glad to say a few words in on the construction of the screen; and also to deal with such cases want of complete success as have come under our notice.—Yours faithfully,

THE THAMES COLOUR PLATE CO.

254A, High Holborn, London, W.C., Nov. 21, 1908.

### DETERIORATION OF NEGATIVES.

To the Editors.

Gentlemen,—I read with interest your article on this subject and your suggestion for testing the effectiveness of the varnishing. My experience, however, is that if by any means the negatives get wet either by soaking up condensation that may run to the bottom during violent changes of temperature, such as we had a fortnight or so ago or whether by drops of water accidentally splashed on the surface those negatives that are not varnished at all fare the best. You will find, I think, in the former case that the damp acts very singularly on the varnish, causing it to make such marks that no amount of doctoring will remedy. I enclose the bottom part of a 1-1 negative to explain my meaning. You will perhaps say if this film had been cut off as you suggest prior to varnishing it would not have happened but I question it, for this reason: I had brought me not long since a negative that had been accidentally splashed with water, and probably not observed, and so it had ultimately evaporated, but it left pit marks in the film according to the size of the globule after the style of the marks, though fortunately none were large. The sample sent I admit is rather bad, though it is but one of several that were on the outside of about 500 on shelf. The intense cold of the bulk favours much condensation in extreme changes, such as I have referred to. Whether celluloid varnish would effectually meet such cases has yet to be proved. I think, however, of trying another remedy, which though a little costly, I hope will be successful in at least reducing to a minimum these effects, but it too has to be tested. I am not likely to adopt the method of the waggon painter, as I have a dislike three times the quantity of stuff needed drying in bulk on the bottom edges.—Yours,

OBSERVER.

[The specimens sent by our correspondent are interesting, but they simply show that an unsatisfactory varnish was used. A shell varnished negative will not usually stand the test we gave, though celluloid varnished one should be waterproof. When the lat

varnish is used the negative can be cleaned with a wet sponge without any fear of damage. A splash that is allowed to dry by evaporation is, of course, a severe test, but we quite expect that a fairly thick celluloid varnish would resist it. As regards the dripping process, we see no reason why the varnish should be more likely to dry in bulk along the bottom edge of the negative any more than a properly mixed paint. A good deal depends on the consistency of the varnish and upon the time allowed for setting before the plate is stood up on edge. In any case, celluloid varnish is not liable to dry thickly.—*Eds. "B.J."*

## Answers to Correspondents.

*All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.*

*Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*

*Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington Street, Strand, London, W.C.*

*For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.*

### PHOTOGRAPHS REGISTERED:—

*T. P. Clarke, 34, Castle Street, Llangollen. Two Photographs of Sir Theodore Martin, K.C.B.*

*E. B. Hughes, 23, Patrick Street, Cork, Ireland. Photograph of Ernest Temple Thurston.*

*Ward's Studio, 45, Staines Road, Hounslow, Middlesex. Photograph of the Head of a Bulldog, "Grenadier Guard."*

*H. S. Franks, Adelphi Studios, 60, Strand, London, W.C. Three Photographs of Draped Figure.*

*E. D. Lavender, The Studio, Tweedy Buildings, Bromley, Kent. Photograph (Combination) of a Placed Group containing Twenty Photographs of Children, arranged in Rows of Five, one above the other. In three instances an Adult is shown.*

*H. Hilton, 8, George Street, Brighton. Photograph of the Brighton United Tui.*

*C. B. (King William's Town).—About the best formula is that given in the "Almarac" (1909), page 908: 10 per cent. iodine solution in potass iodide, 30 minims; 10 per cent. potass cyanide solution, 10 minims; water, 2 oz. As regards the lenses, it is contrary to our rules to give information which is contained in manufacturers' price lists. We have asked the firm in question to reply to you direct.*

*CLOSED STOVE.—I have just put a slow combustion stove, burning anthracite coal, in my work-rooms. Do you think that any fumes from it would injuriously affect bromide prints when drying in this room? It is a closed stove.—F. G.*

Certainly not. The stove should not give off any fumes at all, and even if a back draught should lead to occasional escape of burnt gas the effects on bromide prints would be absolutely nil. A couple of gas-burners of the flat flame type generate more injurious gas (i.e., containing sulphur) than such a stove, and photographic prints are, of course, not susceptible to change from such a cause.

*ENLARGEMENTS.—(1) The best way to get best results in enlarging large pictures 20 x 16 and upwards? (2) Is daylight enlarging through camera without condenser preferable to enlarging camera with condenser and artificial light?—DON.*

(1) The result is chiefly dependent upon the sharpness and softness of the negative. For such large work a thin negative and a powerful light is more necessary than for a lesser degree of enlargement. (2) Both are regularly employed by commercial enlargers, but we should prefer the arc light to daylight for varied trade work. Mercury-vapour lamps are now used considerably without condensers.

*WORRY.—(1) Practice and natural aptitude are the best teachers, but you may derive help from such books as: "The Studio, and*

*What To Do In It," by H. P. Robinson (Iliffe); "The Pose in Portraiture" (Dawbarn and Ward, 6d.); "Lighting in Photographic Studios," by Duchochois. (2) The most useful illustrated work is "Photograms of the Year" (Dawbarn and Ward, 2s. net), just published.*

*EXHIBITION PRINTS.—(1) I am thinking of sending several pictures to the Manchester Exhibition next month, and should like to know whether sulphide toned bromide prints are suitable, or would they stand a better chance if produced in carbon or ozobrome? My reason for asking is that I have them already completed in bromide, and should have to reprint them. (2) I should be much obliged also if you could give me some rough idea as to an average price to ask for pictures about 20 x 15 and 15 x 12 prints, in good oak frames and mounts of the best quality. My reason for asking is that, although an enthusiastic photographer for many years, I have not thought of exhibiting before. I might mention that I do not go in for any hand-work beyond spotting.—W. DE W.*

(1) It is purely a question of effect, and presumably, as you are accustomed to bromide, you will succeed better with that process. The "quality" of a carbon or ozobrome print is better than bromide (each process at its best), but a large proportion of exhibition work is done in toned bromides. As regards price it is found that framed prints offered at much over a guinea do not sell readily. (2) The paper you name is a standard make, and largely used by the photographic profession.

*GUNN AND NOWELL.—Certainly, it is. You may safely entrust them to Mr. E. W. Foxlee, 22, Goldsmith Road, Acton.*

*COLLODION PAPERS.—(1) I have such a trouble with the C.C. papers chipping and peeling, and yet I don't like to give them up, as I get better tones on the P.O.P. matt paper. Is there a means of hardening the surface? (2) I sometimes think of giving albumenised papers a trial, as I have seen prints on them years old a splendid colour and not the least faded. Can you by ready sensitised, like P.O.P., and in a matt surface, and what is the best toning bath for it?—WEEDEE.*

(1) Cracking is often due to using the paper too fresh. If the tubes be opened and the papers allowed to ripen a few days before use the trouble often disappears. There is no other remedy except changing to a brand of paper less liable to this defect. (2) Messrs. John J. Griffin and Sons, Ltd., Kingsway, London, supply an albumenised paper of the glossy type.

*TONING P.O.P.—Re fixing prints before toning, can you tell me what combined bath Professor Namias uses after the hypo-boric acid bath, or would any combined bath answer? It seems contrary to all former teaching to keep this after use and add gold. (2) Would an ordinary hypo bath answer as well as the boric acid one if the prints were washed between?—WEEDEE.*

(1) So far as we know, no special formula for the combined bath is employed. As regards keeping, the conditions are different; the prior fixation removes acid salts from the paper, and the combined bath is thus less liable to decomposition, as pointed out by Professor Namias. (2) We believe it would.

*OLD NEGATIVES.—I believe I saw a reply to a query re address of purchasers of old negatives, but I cannot find it. Would you oblige by repeating it?—G.*

Bowen, 58, Grove Road, Holloway, N.

*READER.—We do not undertake analyses of water. If you told us what specific object you have in view we could perhaps advise you; otherwise your best course would be to apply to, say, one of the Local Government Board analysts for the county of Cornwall. Dr. Bernard Dyer, 17, Great Tower Street, London, E.C.*

*BURSTING SHELL.—The enclosed photograph shows the effect of a shell bursting after it had embedded itself in the timbers of an old wreck which was sometimes used by artillery as a target; a large portion of it was sunk in water and quicksand. Do you think a shell would produce an effect like this under those conditions? What sort of a lens would have to be employed to be at a safe distance, also state distance it might have been taken from, and if you think it has been "faked" in any way.—LYDITE.*

We see no reason to doubt the genuineness of this photograph. If the vessel was partly sunk the effect of the shell would be much the same as that of a torpedo, and the effect represented

reminds us very much of a torpedo explosion. As regards safety of position the photograph might have been taken from an ordinary bomb-proof shelter close at hand, or with a very long focus lens, or possibly it is an enlargement. You must, however, remember that the effect of such an explosion extends up to an immense height, and it is not impossible that the exposure was made in an ordinary hand camera some considerable distance away.

**TICKA CAMERA.**—Will you kindly send me the name of maker of the small Ticka or watch size camera with which Her Majesty the Queen obtained so many of her views?—**RUSSE O'LEARY.**

Messrs. Houghtons, 88-89, High Holborn, London, W.C., are the makers of the "Ticka."

**VARIOUS QUERIES.**—(1) I am desirous of starting business on my own account, but am somewhat uncertain as to how I should set about it. I am at present employed as operator with a certain firm, but I take it that I am not at liberty to use prints off negatives which I have taken here as specimens, even although I intend starting in a town a long way off. How then am I to fill my show-cases, etc.? (2) Supposing I started in a town where there is already a photographer of the same name as myself. If he puts the name on his mounts, say, as "Brown, Whithorn," or "J. Brown, Whithorn," could I name my mounts "Brown, Whithorn"? Of late I have had considerable trouble with a yellow stain appearing round the edges of my plates during development. My formula is (a) 4 oz. soda sulphite, 1 oz. pyrogallie acid, 60 grs. potash bromide, 80 oz. water; (b) 8 drachms liquid ammonia (.880), water 15 oz., using three parts (a) to one part (b). I have sometimes to photograph in bad light, and was of the opinion the stain was due to forcing development with ammonia. I omitted the bromide from the (a) solution and diluted the developer with warm water, but without effect. Would a pyro-soda developer be a remedy, and if so, can you give me a good formula for Royal Standard E.R. plates?—**STAINED.**

(1) You are certainly not at liberty to use the prints unless you have the permission of the firm to do so. Your best way will be to take the specimens in your own studio when you have it ready.

(2) You can, of course, use your own name, but you must not do it in such a way as to lead the public to imagine that you are the other Brown, or are in any way connected with him. (3) We should advise you to try pyro-soda. You cannot do better than employ the formula as issued by the makers of the plates.

**COLOURING POSTCARDS, ETC.**—(1) Can you tell us what dye colours are used for the postcards of actresses, etc., that are shown in shop windows, as these seem to retain their colour very well? We have been using photo-tints, but find that they fade out almost as they dry, and we have had several of the cheaper forms of pendant miniatures returned on that account. We print the picture on bromide Nikko paper, developed with metol-hydroquinone, and fixed in an acid fixing bath and washed as usual. Do you think the acid would have any effect on the permanency of the dye colours? (2) Can you give us the address of a firm who supply tissue paper for interleaving folio mounts, etc., that has somewhat the appearance of watered silk? We have seen this in a photographer's window, but cannot obtain same locally. (3) Also can you let us know of a firm who supply thin vellum or a good imitation of same for mounting purposes, in sheets about 16 x 12, or 22 x 16, or thereabouts, at a reasonable price?—**TISSUES.**

(1) The Vanguard Manufacturing Company supply a reliable series of dyes. The most advisable colours are those printed in italics in the table on page 822 of the forthcoming "Almanac" (1909). The mode of preparation of the print, supposing the operations are properly carried out, will not affect the permanency of the dye. (2) Try F. E. Jones and Co., 22, Gray's Inn Road, W.C. (3) The genuine Japanese vellum, which is expensive, may be had from Messrs. Crompton Bros., Queenhithe, E.C., but they only supply in wholesale quantities. We believe, however, that the Autotype Company, 74, New Oxford Street, supply the same paper retail.

**CARBON PRINTING TROUBLES.**—In my business I work the carbon printing process, but to only a limited extent, say about half a dozen to perhaps a dozen prints a day. During the last month or so I cannot get the tissue to dry after sensitising within a reasonable time. I may say that I have no suitable place for drying it at this time of year, though it is all right in summer. I have a small gas

stove in the room, but the fumes from it make the tissue insoluble when it is dry. At present, if the tissue is sensitised in the evening, it is not dry until nearly the next evening, and is then almost useless unless very hot water is used for the development.

**CARBO.**

In place of the gas stove we should advise you to try a good paraffin stove; the fumes from that will not injure the tissue. Or, better still, use the spirit sensitiser as sold by the Autotype Company. Tissue sensitised with that dries in about a quarter of an hour, and is then in good condition and ready for use. As it is applied with a brush it is not expensive to use.

**L.C.C. LANTERN SLIDES.**—It was reported, at the meeting of the London County Council on November 24, that the Education and Local Government, Records, and Museums Committees had co-operated in a scheme for the provision and circulation of lantern slides amongst the Council's teaching staff by lending all suitable negatives in the Horniman Museum, subject to the museum receiving, as well as giving, lantern slides for teaching purposes. Certain exhibits at the museum are being photographed and reproduced on lantern slides in a scientific sequence for circulation. The exhibits will be grouped in a manner so as to be included in 200 negatives, and from these negatives lantern slides will be made and included in the Council's collection now in use in connection with the lantern slide scheme.

**PHOTO PRINTS FOR BUILDING PLANS.**—At the last meeting of the Buildings and Improvements Committee of Wimbledon Town Council the Town Clerk submitted a letter from the Local Government Board enclosing copy of a communication received by them from Messrs. Niven and Wigglesworth, architects of a house proposed to be erected in Murray Road, complaining that the Borough Surveyor declined to accept plans of the house, on the ground that they were photographed on cloth, and were not "drawn in ink on tracing cloth," as required by the by-laws as to new streets and buildings in force in the borough. The Borough Surveyor, having reported on the facts, the Town Clerk was directed to inform the Local Government Board that "photo-prints" are accepted under the by-laws, so long as they are clear and permanent.

**MIDLAND PHOTOGRAPHIC FEDERATION.**—Although it has only been in existence for rather more than a year the Midland Federation would appear to be in no way behind its older confreres in activity and enthusiasm. Its energetic secretary, Mr. Lewis Lloyd, has sent us a copy of the "Year Book and Gazetteer," the official organ of the Federation, and the long list of societies, nearly fifty, which comprise it, together with the names of the photographic experts who are willing to place their services for either public lecturing or personal advice, at the disposal of these societies, and also their individual members, are evidence that the executive have not been satisfied with obtaining anything less than the best for the benefit of those for whom they cater. Should there be any Midland societies still unfederated they would, we think, do well to send to Mr. Lloyd (Church Road, Moseley, Birmingham, 1s. 1d. in stamps) for a copy of this booklet, a perusal of which will doubtless enlighten them as to the advantages they are missing. The price of the book to members of any federated society is 6d.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

"The British Journal Almanac." The 1909 "Almanac" is now obtainable everywhere. Our publishers advise those requiring it to purchase without delay, since the orders by wholesalers and retailers indicate an even more than usually large demand.

We regret to announce the death of Mr. W. E. Downey. (P. 928.)

Portraiture. The conclusion of the valuable series of notes and hints relating to photographic portraiture is given on page 923.

Some of the minor but important precautions in the making of stereoscopic transparencies are given on page 923.

Among other recent developments in pinatype, Dr. Mees showed the Croydon Camera Club last week the method of stereoscopic projection described by Dr. König in the "B.J." some week or two ago. A demonstration of this kind should make a very attractive society fixture. (P. 926.)

Embossing photographs at the time of dry-mounting, reflex cameras, and folding cameras are among the patents of the week. (P. 923.)

## "COLOUR PHOTOGRAPHY" SUPPLEMENT.

The "Thames" Colour Plate. Our experience with some of the examples of the "Thames" colour plate show it to possess considerable rapidity, but to give more difficulty in registration than may be at first imagined. (P. 89.)

Some interesting photo-micrographs by J. R. and G. R. Lynch and J. H. Pledge showing the structure of the "Thames" plate are reproduced.

Mr. Essenhig Corke has recommended the printing of separate positive transparencies from the negative made through the "Thames" filter-screen in order to obtain several duplicates of one original. (P. 92.)

The kind of positive which should be made for the "Thames" filter is described with other matters by the makers. (P. 96.)

Baron von Hübl, in a further discussion of the properties of the Autochrome plate, concludes that the copy from an Autochrome positive or negative is never quite equal to the original. He takes a highly discouraging view as to the possibility of printing on paper from screen-plates by a leuco process. (P. 93.)

A note pointing out how the Autochrome plate may be wrongly named for black spots upon it occurs on page 95.

## EX CATHEDRA.

### The 1909 Almanac.

Punctual to the announcements which our publishers have made for weeks past, the "British Journal Almanac" for 1909 was on Tuesday last in the hands of the public in all parts of the United Kingdom. Although efforts have been made, both by our publishers and ourselves, to reduce the bulk of the volume, what success has been achieved is, we fear, not very apparent. Nevertheless, dealers and distributors may observe with satisfaction that we have checked the book's corporeal growth, though not, we are assured, its progress and popularity among photographers everywhere. Indeed, if evidence were wanting of the still increasing esteem in which the "Almanac" is held we may point to the ordering of wholesalers, retailers, and importers which led to the edition being out of print more than a week before the day of publication.

### "The Market-Place of the Photographic World."

The volume of the "Almanac" being a kind of stores or shop which is a stranger to early closing and is open all the year round, we have this year—to continue the metaphor—provided a shop-window for the convenience of the purchaser, in regard to which addition it should be remarked that any article not seen therein should be the subject of inquiry to one or other of the firms who are concerned in our composite emporium. The "shop-window," in short, is a classified index to the goods of all descriptions advertised in the "Almanac." An index to advertisers there has always been, but we know it often happens that a given article is required and the name of the advertiser cannot be called to mind. The index, which is placed at the extreme end of the volume, not only does this, but serves also to indicate the choice available in purchasing any given material or piece of apparatus.

### The 1910 Almanac.

It is our usual experience to receive during the months of October and November, or even in December, suggestions from well-meaning persons as to improvements or additions which in their estimation would render the "Almanac" a more valuable work of reference. Not that we resent such suggestions in the slightest; on the contrary, we welcome them, and would be glad to see more of them; but we would point out that they reach us at a time when the bulk of the text portion of the "Almanac" is in the printer's hands, and when, therefore, the duties of revising proofs and dealing with the latest portions of the work are such as do not allow of the compilation of new features or re-modelling of sections. We sometimes gather from these correspondents that they hold the comfortable belief that

on the return of the editor and advertisement manager of the "Almanac" from their holidays somewhere about the end of September, a few instructions to printers, a week or two spent in "general revision," and hey! presto! your "Almanac" is ready to come out. This seems to be the delightful idyllic dream of some of our correspondents, who write us about November 10 with one or two ideas for things that would take a week to compile. To them and to all others we would say:—We invite and consider suggestions, and the best time to send them is the day on which you have gone through the "Almanac" just published.

### More Cine-graph Fires.

During the past week there have been no less than two cinematograph fires in Berlin. But for the extraordinarily strict regulations enforced by the police and a special commission which keeps a sharp eye on such public entertainments, the second fire might easily have had serious consequences, as it happened during a crowded performance. A section of the German press has dealt somewhat sharply with the matter. Meanwhile the authorities are seriously investigating the causes of these fires and their prevention, and are considering the advisability of making it an absolutely necessary condition in the permit to hold cinematograph entertainments that only fire-proof films are to be employed. They are determined to put a stop to these dangers to life, and it is practically certain that some very radical reforms will be introduced in the near future.

\* \* \*

### Pyro Soda Formulæ.

We often hear speculations as to how far the various published formulæ of the different plate-makers really differ, and even hear doubts expressed as to whether they differ at all in many cases. The point can very well be tested by studying the formulæ in the "Almanac," and for this purpose we have abstracted and revised the pyro soda formulæ until they are all reduced to a common measure for comparison. We selected only the formulæ in which metabisulphite is used as a preservative, and of the eight to be found we rejected one on account of vagueness, and one that is conspicuously different from the rest as regards concentration. Of the remaining six, two are practically identical, though this fact would never be suspected from the form in which they are written. In five of them the carbonate is eight times the weight of the pyro, and in the exception it is just about seven times. In four cases both the quantities and relative proportions of pyro and carbonate are the same, and also in four cases the weight of sulphite is equal to that of the carbonate. One of the six formulæ has no bromide, but three of the other five formulæ have the same quantity.

The greatest differences are in the quantities of metabisulphite, which varies from  $3\frac{1}{2}$  to  $7\frac{1}{2}$  grains per 10 ounces of mixed developer. Where so many quantities agree, it is not much use taking a strict average among the whole, and the following formulæ more truly represents what the majority evidently think to be about the correct composition of a pyro soda developer.

Pyro ... ..	27½ gr.		2½ gr.
Potash metabisulphite ... ..	5 "		½ "
Soda sulphite ... ..	½ oz.		22 "
" carbonate ... ..	½ oz.		22 "
Potass bromide ... ..	3½ gr.		1 oz.
Water to ... ..	10 oz.		

In the whole nine formulæ in the book, only one omits bromide, which is rather a curious thing, seeing that a few workers now advocate the use of any bromide at all with pyro soda. In seven the sulphite and carbonate are together in the same stock solution. In one the sulphite is in a separate third solution, and in one it is in the same bottle as the pyro and metabisulphite, which we think, by far the best place for it. Another curious feature is the concentration, which is certainly greater than that commonly used. Two grains of pyro per ounce of developer is very commonly used, but the majority of these formulæ recommend  $2\frac{3}{4}$  grains, and while none goes less, one goes up to nearly  $4\frac{1}{2}$  grains per ounce. As regards mixing, a preference is shown for two solutions used in equal parts, which is perhaps not quite the best arrangement, as it affords no opportunity for warming the developer by adding warm water. We always prefer two solutions of double strength, so that one part is taken of each and then the mixture is diluted with two parts of water.

### Illegal Failures with P.O.P.

Last week our "Patents" column contained an abstract of a curious patent which suggests that the inventor is endeavouring to turn to account a rather common mishap. We frequently have queries relating to the sticking of P.O.P. prints to the glass upon which they are squeezed for glazing purposes, but few have probably realised that this sticking propensity was a suitable subject for a patent. The inventor dips his P.O.P. print into water at 70deg., and then squeegees it on to clean glass. He does this for the purpose of inducing the print to stay on the glass, whereas others in summer weather do precisely the same thing under the impression that when the print dries it will leave the glass and show a fine glossy surface. When the water is really 70deg., and the print has not been hardened, the final result is a little uncertain, but in future photographers will do well to remember that when the prints stick they are infringing this patent. On the other hand, when the patentee's prints refuse to stick, he will have the consolation of possessing some well-glazed results.

## THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1909.

Edited by GEORGE E. BROWN, F.I.C.

### NOTICE.—IMPORTANT.

Our publishers ask us to inform agents that the entire edition of 25,000 copies of the "Almanac" is now booked, and they regret being unable to execute further orders.

The forty-eighth annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC has now been published. Last year's ALMANAC reached a total of over 1,000 pages, and the entire edition of 25,000 copies was sold out immediately. Of no other photographic book ever issued can two such unique facts be recorded. The edition for 1909 also consists of 25,000 copies.

The editorial article deals very completely with the important subject of

### REFLEX CAMERAS,

and the systematic review of the work of the year under the title "Epitome of Progress" is again a strong feature of the volume.

The lines followed in the previous editions of the ALMANAC are maintained in general, but in a number of particulars the arrangement of the volume for 1909 is modified to make it more than ever the book of universal photographic reference.

The ALMANAC for 1909 thus appeals to photographers all the world over as a daily reference guide in practical work. The standard matter and formulæ are revised and added where necessary, and wherever practicable, new features of an informative nature added.

### STEREOSCOPIC TRANSPARENCIES.

MANY photographers have very confused ideas upon the subject of mounting stereoscopic prints, and, owing to the repeated insistence of text-books upon the necessity of separating the two pictures and reversing them right and left, some have an idea that the right and left hand pictures get transposed in some very mysterious fashion. It is easy to produce satisfactory card slides by simply following instructions in a mechanical fashion without understanding the why or wherefore of any of the proceedings, but when transparencies are in question want of knowledge of the true reason of the reversing process may lead to the needless cutting of the negative. As a matter of fact, though we must cut either negative or print when making a card slide from the original negative there is no need to cut either when making a transparency.

The simplest way to look at the cutting question is as follows:—In the first instance, when we focus on the subject, each half of the focussing screen shows an inverted image. If the finished negative is examined through the glass with the right-hand print still on the right we see exactly what we saw on the focussing screen. If, again, we make a print and look at this with the right-hand picture on the right side we still have two inverted images. What is wanted is evident. We must divide the pair of pictures and turn each one separately the right way up and then we have the two correctly arranged.

A very little consideration will show that the inversion of the image that we have to effect is precisely the kind of inversion that takes place when we produce a transparency by copying from a negative in the camera. If, then, we set up our stereoscopic double negative in a copying frame and produce a transparency from it in a stereoscopic camera so that the right-hand lens makes a copy of the right-hand picture and the left-hand lens one of the left-hand picture, the result will be a complete stereoscopic slide with the two pictures in their correct relative positions. No cutting is required and all the necessary inversion is automatically effected in the copying process.

If the negative is set up with the film side towards the camera the resulting positive will have to be viewed through the glass, but if the negative is turned glass side to the camera the positive must be viewed from the film side, which means that the cover glass must be between the film and the eyes when we study the finished slide. The latter is the best arrangement if a ground glass backing is not required, but if ground glass is necessary then the complete slide will have three thicknesses of glass and be very heavy; probably also too thick for the grooves of the stereoscope. The first method of copying, with negative film towards camera, is therefore the best

if a ground glass backing is to be used. This leads to a little minor trouble with the masking, which always looks most neat and gives the best finish when seen through the cover glass. Probably the best effect is produced when paper masks are dispensed with. A very good way is to specially prepare the negative by cutting a clear mask around the images. First mark out with pencil the boundaries of the two pictures, and then with the aid of a straight edge cut through the boundary lines with a very sharp knife and finally scrape away all the film outside the cuts. This is a very easy and safe operation, but when finished the whole negative should be varnished to prevent the edges of the film lifting. The positive made from the prepared negative should then show a black mask in silver deposit, or if the mask does not develop quite black enough it can be easily covered with a coat of black varnish.

It is obvious that instead of making a transparency to be viewed through the glass we can apply Mr. Carnegie's reversing process, and so get a negative from which we can make direct paper prints that will require no cutting. When a large number of prints is required it would be quite worth while to adopt this expedient.

It can, of course, easily be understood that when we dispense with cutting either negative or print we also lose all opportunity of correcting wrong alignment of the two images. To preserve correct alignment it is essential that the two lenses of the stereo camera should be exactly on the same level. That is to say, the axis of each lens when produced to cut the plate must intersect it at the same distance from the top or bottom. This will be the case in any good quality apparatus, but rigidly accurate fitting is not always in evidence in cheap apparatus.

As regards securing proper separation of the images in the transparency, this can be easily arranged in the copying operation if the lens separation is adjustable. If not adjustable the separation for distant objects in the final transparency will be the same as that of the lenses, which must therefore not be too far apart. Some cameras have a fixed separation of  $3\frac{1}{4}$  inches and this will probably be a little too much for the final slide. For an ordinary prismatic stereoscope the distance should not much exceed three inches and for lenticular stereoscopes  $2\frac{1}{2}$  to  $2\frac{3}{8}$  inches is about the limit. If the original separation is three inches we should have to copy with a lens separation of  $2\frac{1}{2}$  inches to give a positive separation of  $2\frac{1}{2}$  inches. An adjustable separation is in all cases desirable, and it can be arranged for without any great difficulty in most stereo cameras. Of course double extension is required for the copying process, unless a pair of very short focus lenses is available, and on this account a  $\frac{1}{2}$ -plate camera adapted to take  $6\frac{1}{2}$  by  $3\frac{1}{4}$  plates is more generally useful than one of the standard stereo size.

### HINTS ON PORTRAITURE.

[In the 1909 "American Annual of Photography," just published, we find a compilation of rules and counsels prepared with evident care by J. W. Little. There being many of the younger generation of photographers by whom such epitomised opinion is welcomed as an aid in their own study of portraiture, we last week commenced the reprint of the article, which is here concluded.—Eds. "B.J."]

PLANT things, such as chiffon, lace, furs, etc., lend themselves more readily to grace of outline than do silk and satin, while dull cloth is more conducive to breadth.

Care must be taken in arranging the accessories, such, for instance, as a newspaper or book held in the hand, that the attention may not be drawn away from the head. Balance may often be secured by the introduction of a strong light by the

use of some accessory or otherwise, to serve as a background for the head, the secondary light being toned down, and so concentrating the interest in the head and face. There should be but one leading light, which should usually be the head, and one leading line, which should lead toward the head; a study of inverted photographs is useful for the purpose of determining the abstract quality of lines and spaces.

The accessories should be employed to repeat the lights. The light of the face should be several times repeated throughout the picture in fainter tones, but there should be no exact quality in any of the repetitions, neither should there be too many, but the chief mass of white should be sufficiently pronounced and have no rival.

Be careful to have the background and accessories suited to the character of the sitter and his costume. Models should also fit their occupation; as, for instance, a tennis girl should be well formed physically.

Jewellery should usually not be worn unless it be of a character that will photograph well and not reflect the lights strongly. Should it do so it should be remedied in retouching.

### Hands.

As a general rule, the hands should not be placed directly below the head, although one of the hands might be so placed if the other carried the greater interest, as might be the case were it holding a book, etc., and the lines running towards it from the head were stronger.

The hands should not be placed opposite each other, nor, when considered with the head, form a triangle or other geometrical outline. Sometimes it is better to subordinate them in tone; to that end they may be placed in shadow and should usually show the edges only. The fingers should be partly folded, but should rest naturally.

If the hands are placed close together, they are likely to be too insistent, unless skilfully posed and subdued in lighting.

The background for the hands should be carefully considered. If the hand touches the face it should not press so hard as to cause distortion of the features. In this case the hand and the side of the face with which it comes in contact may be placed in shadow.

First allow the sitter to drop his hands in his own way, as the result will probably be more natural. If unsatisfactory, they may then be posed or omitted.

Poses of the hands adopted in painting cannot always be followed in photography, on account of the exaggerated perspective produced by the lens and for other reasons.

It is not advisable to use the swing back to get the hands in focus, as it further increases the size of the hands. It should be remembered here that the length of the hand from the wrist is almost the same as from the forehead to the chin.

### Lighting.

In order to preserve tonal values and still concentrate the light on the face, it is better to do so by placing the face in strong light than to darken the tone of the hands artificially.

A vertical light is best for a round face, to give relief. A front horizontal light is best for heavy eyebrows, sunken eyes, and prominent features. A top light gives better character to the eyes, but is apt to exaggerate the mouth. Where there is little projection to the brows, a top light may often be used to advantage.

If the arrangement of the blinds to secure proper lighting be once ascertained, almost any effect can be secured by moving the sitter and by the use of head-screens, without moving the blinds.

Some operators consider that the best effect of lighting is secured when the catch lights fall on the eyes properly, securing the different effects, such as broad lighting, Rembrandt lighting, etc., by moving the camera around the sitter. For most lightings, the subject should look forward with the face about parallel to and slightly back of the side-light, with the light falling upon the head at an angle of about sixty-five degrees.

For diffusion of lighting, some operators use a large screen composed of tracing cloth, which is interposed between the skylight and the sitter in such a manner as to shut out all direct illumination excepting that which is permitted to pass

through an aperture about two feet square in the centre of the screen. Others use an open light, corrected by opaque screens between the subject and the light, to produce luminous shadows in the subject and at the same time allow of short exposure.

If the lighting is harsh, lengthen the exposure and shorten development; if flat, shorten the exposure and lengthen the development.

Softness may be produced by removing the subject from the light and allowing a large area of light to enter.

More brilliant lighting can always be obtained on bright days than on dull days, as the light is more diffused, and faster plates must be used in dull weather, which do not give as much latitude as slower plates. If slow plates are used it is often necessary to diffuse the light on bright days to soften contrasts.

When orthochromatic plates are used, the light on the sitter should be screened by pale yellow blinds, when it may not be necessary to use a ray screen over the lens. If panchromatic plates are used such blinds will not be necessary.

If there is no blue or violet in the subject, it is of no advantage to use a ray filter in connection with orthochromatic plates, and they may be used without it; or the light falling upon the blue may be shielded by an opaque screen.

The use of ray filters in connection with orthochromatic plates tends to increase contrasts of light and shade. The lighting then should therefore be somewhat more diffused.

Orthochromatic plates are not always desirable in portraiture, as in the case of contrasting blue and white stripes, which might be rendered too contrasty. The use of orthochromatic plates, however, tends to minimise the necessity for retouching. Flat lighting on the shadow side of the face is more suggestive of youth; more contrast is suggestive of age and character.

Thin faces should have diffused lighting, which tends to make them look more full, while hard lighting tends to give more expression to round faces.

High-lights upon or surrounded by light tones give suavity and gentleness of modelling. In a face this lighting produces flatness, and is therefore adapted to faces which are wrinkled and thin, where these qualities are apt to appear too pronounced.

High-lights against deep shadows give brilliancy and produce ruggedness and angularity. This is a good lighting for faces inclined towards flatness or having little elevation of the features, and tends to bring out expression.

A flatter lighting is required for a profile than for a three-quarter or full face.

The more at right angles the light, sitter, and camera are placed with respect to each other, the longer the exposure required, on account of the greater portion of shadow showing in the portrait.

Reflectors are useful for lighting up shadows cast on backgrounds or other portions of the picture. A note should always be taken as to what extent the reflector throws light on the background as well as on the sitter.

### Reflectors.

To avoid giving a harsh light, the reflector should be large and at some distance away. When used for the head and shoulders only it should be small, close to the subject, and just out of range of the lens.

A pure white reflector is apt to cast too strong a reflection on the shadow side of the face, producing second catch lights in the eyes.

A reflector on the floor will reduce shadows under the chin and nose.

When a white screen is used between the subject and the light for diffusing the light, the exposure may be somewhat less.

When using a white side screen for diffusing it is sometimes

useful to have one or two very small dark screens to cut off the light from the shoulder or from the hands in case they should be posed against a dark ground.

In general, the principles governing the lighting and posing of a portrait in the studio will also apply to portraiture by an ordinary window, although, the source of light being smaller and less under control, it is more difficult, and effects cannot be obtained in such variety.

Owing to the concentrated lighting when using an ordinary window, the scale from light to dark in the composition should be short; the subject should be as well lighted as possible, the light diffused, the shadows illuminated by reflectors, and the exposure ample.

A sheet of white cardboard may often be placed outside the window at an angle to secure better lighting where the light is obstructed by high walls or other objects.

A shaded window at a considerable distance on the opposite side of the room may often be utilised to light the shadow side of the face, but the light from it should not be so strong as to produce flatness or cross lighting.

If the walls of the room are too light, or the light from other windows in the room is strong and difficult to control, a dark reflector may be used to tone down the light on the shadow side of the face.

If daylight is insufficient in at-home portraiture, the side opposite the source of light may be sometimes lighted by a small supplementary flashlight, using plain magnesium.

By seating the subject low, as with children, he may be placed farther from the window; the farther from the window, the more diffused will be the lighting.

A good lighting may be secured by an ordinary window by placing the subject the same distance from the window as the width of the window and even with its farthest edge. Cover the lower part of the window with a dark shade and raise it to the same height as the head of the subject; then turn the head of the subject until the eye in the shadow can just see the window.

When the dress is dark, the lower part of the window should be covered with some translucent material, in order that the dress may receive sufficient exposure.

Violent contrasts in clothing, accessories, or colour should be avoided or controlled in lighting. A large mass of dark or light, such as a black or white dress, must be partly lost in the shadow or in the background in places, or it must be relieved in some other way, as by a strong effect of contrast. White objects should usually show relief on one side, and on the other unite with the shadow or background to prevent their appearing to be inlaid.

Figures in silk and satin dresses should be so lighted that the face only is in strong light, to prevent spottiness by reflections.

When photographing a subject in a white dress, compromise between over- and under-exposure of the face. Ribbons, etc., may be retouched a little, and the face held back while printing. Woollens and colours which absorb the light require more exposure.

If white drapery must be used, it is better to have it of wool, which absorbs the light better than cotton. Non-halation plates are best. A painter's comb, having about twelve teeth to the inch, placed in front of the upper half of the lens, if properly used, will serve to partially cut off the light falling on the lower part of the figure.

When it is intended to vignette portraits, the sitter should not wear clothing of marked contrasts or patterns; white drapery is perhaps best. The background should be light and plain or somewhat graduated; the light should come rather from the front, the focus should not be too sharp, and the eyes of the sitter should not be looking directly toward the camera; exposure and development should be so controlled that the face

will not appear in the print as very much darker or lighter than the background.

Black vignettes may be obtained by placing a vignetter inside the camera and about two inches from the ground glass.

Vignetted photographs are not particularly in good taste, as they prevent proper spacing and uniting of the subject with the margins of the picture, and, moreover, are apt to convey the impression that they have been printed in that way to conceal defects which would otherwise appear.

When a light background is used the lighting should be flat, and a lighter range of tones should be employed on the face than with a dark background, when the general lighting should have more contrast.

When using a painted background, the light should fall from the same source as the shadows indicate as painted on the background.

Where strong contrasts are desirable, it is usually better to put a light figure against a dark background than a dark figure against a light background.

A dark background generally gives more importance to the head than does a light background. Dark clothes are less noticeable against a dark background and light clothes against a light background.

The figure should usually not show too hard against the background, but should merge into it at some parts to produce one scheme of light and shade.

The background should never show a greater degree of light and shade than does the principal part of the picture.

When it is desired to subdue the background and accessories, negatives may be given a short exposure and shadows strengthened with matt varnish on the back, while detail may be strengthened by retouching on the film side and the portrait printed on rough paper to soften the lines of the retouching. Undesirable portions of the background may be eliminated by reduction; various other modifications may be made also by reduction and spotting, as practised in some studios.

The light and shade values of either plain light or dark backgrounds may be variously modified by setting them at different angles, either laterally or horizontally, with respect to the source of light. This may also be done by reflecting light on various parts of the background, or by screening parts of it from the light.

When graded backgrounds are used, care should be exercised that undue prominence is not given to those parts of the subject coming against the lighter parts of the background. Some operators are opposed to the use of artificial and graduated backgrounds, and use various plain fabrics in their stead. Brown and gray paper often make very serviceable backgrounds.

The distance of the background from the sitter should be studied with the lighting. Atmosphere is more easily secured with a grey background.

A full-length portrait should have plenty of background space.

For a good likeness, a light background is preferable; for a study dark background is usually best.

With a white background, a longer exposure is usually required to avoid contrasts. With a dark background the exposure should generally be shorter, as the lights of the face are then shown with greater clearness. Development in either case should not be prolonged.

If a background has creases in it, it may be kept moving during the exposure.

A simple background may be improvised by the use of the open doorway of a darkened room, or the door itself, by a suitable choice of angle, may be made to act as a graduated background.

When taking a portrait outdoors it is often better not to attempt to pose the subject, but to await a favourable opportunity, and then snap the shutter.

When a bust picture is taken outdoors it is sometimes better to have the subject standing.

J. W. LITTLE.

## RECENT DEVELOPMENTS IN PINATYPE AT THE CROYDON CAMERA CLUB.

[Dr. C. E. K. Mees, on the 25th ult., chatted informally and interestingly about pinatype, as applied to three-colour slides and prints, stereoscopic projection, and monochromatic transparencies and paper prints. As a rule, the optical lantern, the blackboard, and a plentiful supply of white chalk, are sufficient to meet the learned doctor's requirements; but on the evening in question, in addition to these almost indispensable adjuncts, a fine array of dishes, measures, and various coloured solutions indicated something in the nature of a "practical demonstration," something indeed which the own gratification, and equally to others who would in turn combat his views. A cheerful, as well as an instructive, evening was therefore anticipated, and, as a matter of fact, realised.]

DR. MEES, after introducing his remarks by some description of the large scale on which dyes were invented and manufactured by Meister Lucius and Brüning, turned to the subject of the evening, incidentally reminding his hearers that the first demonstration of pinatype in this country was given at the Croydon Camera Club, since when, although no startling innovations had been effected, much patient work had been done towards perfecting the process. Pinatype, as they knew, depended upon the fact that a bichromated film, when exposed to daylight behind a positive, is capable of taking up a dye out of solution, in inverse ratio to the light transmitted, and in consequence reproduces such positive.

### Three-Colour Lantern Slides.

In the making of a three-colour lantern slide three positives from the original negatives were therefore necessary. As pinatype was capable of reproducing gradations very faithfully, a positive of fair, but not excessive, contrast should be sought for, not the soft and flat transparency usually employed for enlarging by artificial light. A bichromated film on glass is exposed behind the positive from the red filter negative and dyed up blue; the film is then coated with a layer of plain gelatine, sensitised, and exposed behind the positive from the blue filter negative and dyed up yellow. The third transparency is printed on a separate plate, from the positive taken from the green filter negative, and dyed magenta. As this forms the cover-glass a reversed positive is required. Immense trouble had been taken by Dr. König and those working with him to secure suitable and permanent dyes. Apart from the extreme importance of their possessing correct colour absorptions, it was also obligatory that they should not spread laterally in the film or wash out. All "acid" dyes could be used, but it was not worth while considering other than those specially sold for the purpose, which naturally were much the most suitable. Plates coated with plain gelatine were obtainable, and must be sensitised by bathing. It was not convenient or conducive to satisfactory results to attempt to incorporate the bichromate salt with the gelatine before coating.

### Three-Colour Paper Prints.

Three positives are required as before, except that the necessity for reversing one does not arise. They might be obtained either by enlargement or by contact from the original negative. Three bichromated films on glass are exposed and dyed up as usual and washed. It was a strictly necessary condition that the "print-plates" be coated with a hard gelatine. A piece of paper coated with soft gelatine is then immersed in water and applied to the print-plates in the order given in the instructions, when the dyes are successively absorbed by the soft gelatine to any required extent, which may be gauged from time to time by inspection. It was essential that the paper be thoroughly saturated and applied to the print-plates under water and kept damp whilst in contact. The print-plates might, of course, be used over and over again by repeating the dying-up.

### Transparencies and Prints in Monochrome.

The same system, *mutatis mutandis*, might be applied in the production of monochromatic slides, transparencies, and paper prints. A very large number of special dyes were available of every variety of hue. These were divided by Dr. König into two classes, the first comprising dyes which severe tests had proved to be permanent, the second being dyes which experience had shown were not so stable, but might be used with confidence for lantern slides. Absence of grain, with great transparency, characterised "pinatype" slides. The process, moreover, was inexpensive to work, notably so in the case of paper prints, when a paper of far less purity might be employed than could be adopted for coating with a silver emulsion. For the cheap production of postcards it merited consideration and for repetition work with lantern slides.

### Novelties in Colours.

A series of slides, in three-colour and in monochrome, were then shown on the screen, and comprised some very beautiful subjects. In the monochrome set fine rich blacks, brown-blacks, browns, and olive-greens were much admired. Next came such illustrations as seascapes in bright crimson, spring landscapes in intense purple, the setting sun in sullen indigo, portraits in pea-green, and so on. These, the lecturer explained, somewhat nervously, were not shown as examples of appropriateness in colour selection, but rather as indicating the wide range of colours obtainable. Notwithstanding this explanation, an excellent simulation of wrath amongst the pictorialists present at once became evident. One after the other they rose and went for the devoted doctor in right royal fashion. A chance like this was not to be missed, and it was felt that the most must be made of it. During this outrage on the finer feelings of the artistic temperament an interested point was elicited in respect of a few of the black dyes. These—unlike a platinotype black, for instance, which absorbs the spectrum fairly evenly—possess only absorption bands, and in consequence a decided change of tint occurs when the former is viewed in some artificial lights. It was also pointed out (possibly as a sop to the inflamed pictorialists) that a considerable amount of control was obtainable, over-exposure giving hard results, under-exposure the reverse. The correct exposure for a slide might be taken to be about twice that, which would be given to P.O.P. for full printing.

### Stereoscopic Projection.

Undoubtedly the chief interest of the evening centred in this. In principle the method is old, but it may safely be asserted that it has been brought to a state of perfection never before attained. It consists of the projection by means of a single lantern of two coloured pictures in close juxtaposition, which are viewed through spectacles having eye-pieces of similar colours: Two pinatype slides are made, one in the usual way, the other forms the cover-glass, and must necessarily be printed from a reversed positive. These are respectively dyed in two colours, which have only just been placed on the market—viz., "complementary green" and "complementary red"; the two plates are then bound up in the "nearest approach." To obtain a satisfactory red, the lecturer said, was fairly easy, but up to the introduction of "complementary green" there was no dye extant which would fulfil theoretical requirements. When the two overlapping pictures are projected as one on the screen a little fuzziness only is apparent, or, rather, the slide has the appearance as if the camera had been slightly moved during exposure. The spectacles, which gave the company a very distinguished and unusual appearance, are constructed out of cardboard and string. One eye-aperture is glazed with red gelatine, which, to all intents and purposes, only allows of the green image being seen (as "black"), the other is glazed with green, which only permits the red image to be observed (also as "black"). The eyes therefore resolve the composite picture monochromatically and with true stereoscopic effect. It is obvious that all the spectacles must be worn one way and in accordance with the projected images. In the case where, say, some isolated branches of a tree or other objects much nearer to the camera than the rest of the view were included, then the appearance on, or rather away from, the screen was very curious, not to say, startling. Such branches or other objects appeared to shoot out of space well in advance of the screen and to be quite independent of the picture behind them. This method of stereoscopic projection seems well worthy of the attention of amateurs and others, and will undoubtedly come as a novelty to the majority. From the foregoing it is apparent that no difficulties worthy of the name exist, and no special apparatus is required,

of, of course, the spectacles, which, so far as the cardboard frame concerned, might easily be improvised at home. Possibly they supplied ready made, and no doubt the London agents for pinaktes, Messrs. Fuerst Bros., would be happy to answer any inquiries. Already stated, the method is not new, since it dates back to Louis Du Haumont, who, under the name of "Anaglyph," introduced in 1891, but hitherto only ordinary commercial dyes and coloured inks have been available, and have therefore imperfectly realised the theoretical conditions.

### CARD-FILING FOR STUDIO BUSINESS.

FOSTER BRIGHAM's article of last week on the use of the card-index system in controlling the production and charging of work in a portrait photographer's establishment naturally attracts interest to the cards prepared by Messrs. Houghtons for general use by photographers. We believe we are correct in saying that Foster Brigham's design of card was not made in ignorance of that of Messrs. Houghtons Ltd., but was drawn up on the lines shown and described in our last issue in order to carry out the system which seemed best to its author. The contingencies provided in the Houghton card, which is an adaptation for British studios of the system described by Mr. Pirie MacDonald, will be

appreciated from the account contained in a booklet "Keeping tabs on your Business," which Messrs. Houghtons will be pleased to send to any professional photographer. This runs as follows:—When an appointment is made the card can be filed according to the date of such appointment and it thus automatically comes to the front upon the day for which the sitting has been fixed. It is next placed behind a Guide (or card with projecting tab) marking proofs are in hand, after which it is moved to division marked "Proofs out."

Should finished proofs have been ordered the particulars must be noted. Should the proofs be detained "Reminders" in the shape of a letter or postcard can be sent enquiring whether they are satisfactory, or if the client would prefer to give another sitting. The proofs having been returned the date is filled in upon the card and the order put in hand. Particulars of the orders will of course be entered in the spaces provided.

As the work proceeds the card will be marked and placed behind the corresponding Guide Cards:—Retouching, Printing, Finishing. As the prints are delivered, the number and dates are filled in, and the card placed in the "Unpaid Accounts" section. The lower portion of the card should be used as a ledger and the items posted on the journal and cash book. If this procedure is followed there will be little or no danger of accounts being overlooked. The Card is finally removed to the Alphabetical Index, where it is always instantly accessible for reference.

The cards as supplied by Messrs. Houghtons measure each 8 in. by 5 in., and are kept in an oak box measuring  $5\frac{1}{2}$  in. by  $5\frac{1}{2}$  in. by 9 in., and accommodating about 300, or in larger and more elaborate cabinets which permit of the system expanding to meet the resources of any business. The single-box outfit may, however, be recommended to those anxious to make a beginning with the system, and in any event is the essential or working part of the system, since it is the indicator which shows how orders stand and what accounts are owing. The file of cards representing work done and paid for may be separately kept as the cards increase without affecting the vital and most useful part of the system. The simplest form of outfit is obtainable complete with box, cards, guides, etc., for 15s., a larger outfit for 42s. What we wrote a year ago of the usefulness and efficiency of such a system needs to be emphasised still more to-day, and we would therefore direct attention to the means thus offered to the smallest photographer of keeping his business under his eye in a way which no other method so easily permits.

## Answers to Correspondents.

*Owing to re-make up of this issue it has been necessary to place part of the Answers to Correspondents here.*

**TRIPLER LENS.**—I have a lens offered me for 12 x 10 pictures. It bears the name of J. H. Dallmeyer, "Triple Achromatic." Will you please say if this lens is as good as a R.R. for outdoor groups and general work? It is offered me cheap, but I want a good lens, and cannot afford the price of one of the new forms of anastigmats. Awaiting the favour of a reply through the "Journal."—A. J. BURGE.

The triplets of Dallmeyer were very excellent lenses for the time when they were introduced, but they have very generally been superseded by the R.R., and still more modern lenses. As compared with the R.R., the triplet is rather a slow lens, as its largest aperture is but about  $f/10$ , while that of the former is  $f/8$ . Still, the triplet is a very useful instrument for general work, where great rapidity is not required, as, for example, in copying pictures. For this purpose it is still much liked on account of the fine definition it yields.

**PAPER FOR BACKGROUNDS.**—Can you kindly tell me of any place where I can get paper, brown, up to 5ft. or 6ft. wide without creases for making backgrounds? I have inquired of several stationers in this neighbourhood, and none of them keep the paper except in sheets, and these are all folded in the middle, which, of course, would not do.—J. G. BELL.

Brown paper, and also a grey, may be had up to at least 5ft. wide and of any length, and is a regular article of commerce. It is supplied by all upholsterers. It is known as "carpet paper," and is made for putting under carpets when they are laid.

**A. Z.**—If you bought the goodwill and books and book debts, together with the furniture and apparatus, the negatives are yours, unless in the agreement they were specially excluded. What would be the use of the goodwill and books without the stock of negatives? We should advise you not to give them up, but to consult a solicitor if you are threatened with action.

**MOUNTING LANTERN SLIDES.**—Will you please let me know the best cement to use for binding up lantern slides? I have used gum—the best gum arabic—and dextrine, but I find the paper has a tendency to peel off with the heat of the lantern.—HANTS.

We know of nothing better than either fish glue or thick flour paste, made with good flour and well boiled. With this there will be no tendency for the binding to split off. Gum is not a good cement for fixing paper to glass.

**E. K. C.**—Both methods are good, and some prefer one and some the other, but the prints strip off equally as well with either. Waxing the plate is a little more trouble than treating it with French chalk. Some who employ the former method say that with it they get a higher gloss than with the latter. As a matter of fact, however, in practice, there is very little difference between the two in this respect.

(Continued on page 935.)

## DEATH OF MR. W. E. DOWNEY.

We regret to record the death of Mr. William Edward Downey, which took place on Monday last, November 30, following an operation. With his father, Mr. William Downey, who is now more than eighty years of age, the deceased gentleman had been associated with the Royal family from boyhood. When twelve years of age he accompanied his father to Balmoral to take a photograph of Queen Victoria, and since then a succession of Royalties and groups of Royal personages have been photographed by the Downeys, father and son. At the time of his death, Mr. Downey was only fifty-four years of age. His decease will be keenly regretted in his family circle, and particularly by his venerable father, with whom wide-spread sympathy will be felt.

## Exhibitions.

## EDINBURGH PHOTOGRAPHIC SOCIETY.

THE annual exhibition of the Edinburgh Photographic Society is still some months ahead, but this month they have in their rooms, 38, Castle Street, Edinburgh, an exhibition of members' work. The membership of the E.P.S. is not confined to the city, its special rates for country members assists greatly in maintaining its high membership roll, and in the prize list we find that a number of the awards have been gained by non-resident members. The President has shown his active interest in the survey section of the society—a branch of work that we have frequently commended—by gaining the medal in that class, besides one in architecture, thus showing that he is not merely a figure-head, but an active working president. The exhibition shows a good level of quality, and should be a popular item in Edinburgh photographic life. Landscape and seascape: Medals, James McKissack (2), Rev. W. J. Hansell, Alex. G. Watson; honourable mention, J. Angus, D. Lumgair. Survey: medal, J. F. Duthie. Architecture: medals, J. F. Duthie and Francis C. Inglis; honourable mention, Miss Grace M. Rae, James McKissack. Portraiture and figure work: medals, Rev. W. J. Hansell (2), James McKissack; honourable mention, James McKissack, Miss Margaret McLauchlan. Colour work: medal, W. Mitchell. Lantern slides: medals, James McKissack (2); honourable mention, J. Angus, J. D. Brown, R. C. Malcolm, James McKissack, Rev. W. L. Jamie.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for Patents have been received between November 16 and November 21:—

**COPYING.**—No. 24,566. Improvements in photographic frames for copying plans, drawings, and the like. Richard James Baker, 156, Llandaff Road, Canton, Cardiff.

**FILM PACKS.**—No. 24,734. Improvements in flat film packs. Jochaim Georg Schneider, 6, Lord Street, Liverpool.

**CINEMATOGRAPHS.**—No. 24,752. Improvements in apparatus for photographing and exhibiting cinematograph and mutoscopic pictures. Henry William Hamblin Palmer, 52, Stephens Road, Tunbridge Wells, Kent.

**FLASH-LIGHT.**—No. 24,831. Improvements in or connected with firing mechanism for photographic flash-light apparatus. Arthur George Barrett, 55, Chancery Lane, London.

**DEVELOPING APPARATUS.**—No. 25,074. Improvements in apparatus for developing sensitised plates. Arthur Augustus Brooks, 57, Barton Arcade, Manchester.

**SPECTROGRAPHS.**—No. 25,095. Improvements in spectrographs. Peter Heele, 16a, Valletta Road, Acton, London.

## COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

**DRY-MOUNTING EMBOSSED FOLDER.**—No. 3,727. 1908. The object of the invention is to accelerate the process of attaching prints

to their mounts by the dry-mounting method, and, at the same time, to emboss or otherwise plate-mark the prints. For this purpose, a folder is used consisting of two plates jointed at one side and made of metal sufficiently thin to be easily bent. The folder is opened and a mount to which it is intended to attach a photograph is laid on one of the plates; then the photograph to be attached is laid on the mount, put in correct alignment, and the other leaf of the folder is gently closed over. The whole is then placed under the mounting apparatus and receives the necessary pressure to secure adhesion.

The plates may conveniently be of different finish to each other, for example, one of them may be highly polished to impart a glossy surface to the print, and the other finely ground or matt surfaced for a like purpose. Or the plates are made with double

Fig. 1.

acting hinges, so that they be folded in either direction, thus allowing of four degrees of finish to their surfaces instead of two as in the former case.

The example shown in figure 1 consists of two plates A, B, having hinges C along one side, and provided near the other with apertures D, with any other convenient device for opening the plates.

In operation, the folder is opened, the mount is placed face upwards upon the one plate; on it is placed the print in proper alignment, the two are held in position with the fingers; the other plate is folded over, its resilience being such that the inner edges of mount and print can be held by its pressure before the outer edges are released by the fingers; and the whole is then placed in the mounting press and pressure applied.

In the example shown in figure 2, a distancing plate E is applied to one folding plate A, and on the other plate B are marked lines G for registration purposes. Or if the hinges C be double acting, the distancing plate and registering lines may be duplicated for folding in the reverse direction. The plate is for the purpose of concentrating the pressure applied upon the print, so

Fig. 2.

that mounts embossed or otherwise ornamented about their borders may be used without risk of their ornamentation being obliterated or damaged by the pressure applied.

In operation, the folder is opened, the print to be mounted is laid face down upon the ruled plate—its position being adjusted in accordance with the ruled lines—the mount is laid face down thereon—its position also being adjusted by the ruled lines; the other plate is folded over and the whole placed in the press and pressure applied. Or alternatively, the mount may be placed in position face up, the print laid thereon—both with due regard to position, and the other plate bearing the distancing plate E folded over. In this latter case the plate E may be surfaced in a manner to give any desired surface finish to the print.

The example shown in fig. 3 is adapted for plate-making, and it may be also embossing the mount. In it there is provided upon the ruled plate B a marking plate H—which may also be surfaced to impress the print. Upon the opposite plate A is a former frame J within which when the plates are folded together

Fig. 5.

the marking plate H fits. A device such as the monogram K may be formed in intaglio in the marking plate H, or be attached thereto, while the counterpart relief L is formed in or attached to the plate A.

In operation, the folder is opened; the print laid face down in proper position upon the marking plate H; the mount—of course of sufficiently thin material—is superposed and the whole closed and subjected to pressure.

It is obvious that the folder and other plates need not of necessity be of metal—they must, however, be of material sufficiently hard to withstand, and sufficiently flexible to allow of the easy handling and placing in position of prints and mounts. George Wilson Morgan, 393, Union Street, Aberdeen.

**FOCUSSED PINION AS MIRROR RELEASE OF REFLEX CAMERA.**—No. 12,925. 1908. The invention consists in the connection of the focussing pinion (or the pinion head) with the releasing catch of the mirror in a reflex camera in order to provide a supplementary movement serving to release the mirror.

The camera may be of any ordinary construction with a swing or pivoted reflector A, a racking front B carried on racks C, and operated by a rack pinion D and a pinion head E. The reflector A may be retained by a lever F engaging its edge or otherwise as in figs. 1 and 2 or by a lever engaging a lever upon which the reflector is pivoted, and such as described in the specification of the former Patent No. 10,469 of 1908 ("B.J." September 11, 1908), or the lever F may act in any other arrangement to retain the reflector in position for focussing.

The retaining and releasing lever F is provided with a pin *f* or other device by which it is brought into contact with the pinion head E to which a sliding movement is given in addition to its rotary movement.

In the construction shown in figs. 1 and 2 the pinion head E is mounted upon the journal *d* of pinion D so as to move to and fro thereon a sufficient distance to press the pin *f* of the retaining and releasing lever F inwards to release the reflector, the mounting and journalling of the pinion remaining as before. A spring *e* returns the parts to normal position.

In the construction shown in fig. 3 the pinion head E is mounted loosely on the journal of the pinion D so that the latter can slide longitudinally therein and a collar *d*<sup>1</sup> on the pinion engages the retaining and releasing lever F. The locking bush

*d*<sup>2</sup> which fastens the pinion head on to the pinion projects beyond the pinion head E and serves as a push.

In the construction shown in fig. 4, the pinion D and pinion head E are rigidly connected and a push *E*<sup>1</sup> is inserted in the pinion head with pins *e*<sup>1</sup> which engage a collar *e*<sup>2</sup> against which the pin *f* of the releasing lever F engages—the spring *e* holding the collar in normal position. By pressing the push *E*<sup>1</sup> the collar *e*<sup>2</sup> is moved inwards to actuate the releasing lever.

Any other suitable form of connection between the pinion D

Fig. 1.

Fig. 2.

and the pinion head E may be adopted which will permit of a supplementary movement either to the pinion head or to the pinion or to both, and such movement may be in either a push or a pull. The same result can be obtained by pressing or moving the pinion head and pinion downwards, the bearing being held in normal position by a spring.

In the arrangement shown in fig 5 the bearing of the pinion D is in a pivoted plate *D*<sup>1</sup> pivoted at *d*<sup>3</sup> and held in gear with the rack C by a spring *c*. To the pivoted plate a lever G is

Fig. 3.

Fig. 4.

Fig. 5.

connected which when the pinion head E is pressed downwards is moved to release the reflector. On releasing the pinion head E the spring *c* carries the plate *D*<sup>1</sup> back and the pinion D into gear again with the rack C.

It is to be understood that any other suitable connection may be made between the pinion head E or the pinion D and the reflector releasing lever so that a supplementary movement of the former other than rotary will release the reflector. And also that it may be applied to any form of reflex or reflecting camera with racking front in which a swinging reflector, swinging mirror or focussing plate has to be released preparatory to the taking of the photograph. Thornton-Pickard Manufacturing Co., Ltd., Arthur Gray Pickard and Frank Slinger, Altrincham, Cheshire.

**STEREOSCOPIC LENSES.**—No. 27,644. 1907. The invention relates to lenses for photographic, stereoscopic and like apparatus by means of which two images of the same object can be superposed on the same plate in such a manner as to obtain negatives or prints giving the effect or idea of relief.

As shown in this drawing (fig. 1), the apparatus comprises two semi-lenses obtained, for example, by dividing a single lens along a diameter thereof; the semi-lenses are placed in such a manner that the faces of the diametral planes of section are opposite to one another. In the case in which these semi-lenses are fixed in circular mountings *b*, the other halves of the lenses

are placed by opaque bodies *c*. The two lenses *a* are placed a suitable distance apart. Behind these lenses are arranged two systems of prisms *d, e*, giving a total reflection, which displace the rays 1, 2 coming from the object, and throw them upon a lens or objective *f* which causes them to converge along the lines 3, 4 to a point *g* on the plate.

The images formed by the rays 1, 2 are thus superposed at the focus of the system which operates as if the two half lenses *a* were united at the front of the lens *f*, but since these rays

Fig. 1.

Fig. 2.

Fig. 3.

1, 2, have a certain separation, the two images, by being superposed, give the effect or idea of relief. These two images not being identical, the rays 1, 2 should not be separated beyond a certain limit, beyond which superposition becomes impossible.

As is seen, this arrangement thus automatically superposes two images at the focus of the apparatus.

Figs. 2 and 3 represent two types of diaphragms or screens intended for use in the apparatus shown in fig. 1. Each screen is formed by two plates *h*, those illustrated in fig. 2 showing an opening at or towards their centres, so that only the rays which are central with relation to the optical system, are utilised. The diaphragm or screen illustrated in fig. 3 is provided with apertures *i* in the form of annular segments which permit only the most refracted rays to be received. These plates are placed between the prisms as shown in fig. 1. Luiz Augusto Teixeira de Aragao, 40, rue Perronet, Neuilly sur Seine (Seine.)

**FOLDING CAMERAS.**—No. 28,464. 1907. The invention comprises various devices to be employed in a very small box or fixed body camera, the body of which forms a spool-holder for the sensitive roll-film. There is provided, firstly, a new form of twin strut for supporting the camera front, made preferably from a single stamping, bent at suitable angles, and provided with ears or lugs which extend beyond the usual limits, and are pivoted externally to the camera body. Some of the advantages of this plan of construction are that the struts, having a longer reach, accommodate a longer focus lens than has hitherto been possible, and the fact of their being of twin like formation, reduces the number of parts, whilst the extended ears or lugs being pivoted externally, to the camera body, simplifies the assembling of such parts. Secondly, a front plate of new design which at once forms a means for opening the camera and a supporting foot for the

said camera when open. Thirdly, a new method of forming the key way in the spools and a simple key for engaging therein, dispensing with the necessity of a sliding key, such as cameras of this type are usually provided with, and which are of more or less complicated construction. Magnus Niell, Djursholm, Sweden.

**WATCH CAMERAS.**—No. 32. 1908. The invention relates to the type of camera made in the form of a watch in accordance with Patent Specification, No. 21,295, 1904. Improvements now made in this description of camera allow of (1) provision within the camera to accommodate a view finder which is made to automatically spring into position by the setting of the shutter. (2). A spring-operated safety cover over the lens-aperture which allows the shutter to be set without admitting light to the sensitive film, and acts as the shutter release when retracted against the tension of the spring. It also performs the function of a time-exposure shutter when the exposure opening of the ordinary shutter is adjusted opposite the lens. (3). A lens situated at the side of camera instead of in the stem as formerly, the stem being utilised to act as the film winder in the same manner as the winding stem of a keyless watch. (4). A novel form of roll holder arranged to lie diametrically within the case of camera, with the focal plane situated at its rear part to preserve the necessary focal distance. Magnus Niell, Djursholm, Sweden.

**AFFIXING CAMERA ACCESSORIES.**—No. 8,201. 1908. The invention relates to the fastening of accessories such as view-finders, vignettters, etc., to a camera. The objects to be fixed, or the rails or the like which support them, are connected with the camera by the means of the usual screw socket or bushes or to the screw which engages therewith.

The device is provided with an intermediate piece which is either clamped between the stand and the camera, or can be fixed as desired to the bottom of the camera by means of a special thread on the stand or by a special bush or screw socket on the bottom of the camera, or to the stand itself. Karl Lenck, 154, Friedrich Strasse, Berlin NW 7, Germany.

**NEGATIVE WASHER.**—No. 13,281. 1908. The claim is for a washing tank in which the negatives themselves are held in place against the corrugated inner face of the movable cover by a series of spring-pressed clips. The negatives are thus carried into position within the partitioned receptacle when the lid is closed thereupon, and will be removed therefrom at the completion of the washing process.

Means are further provided for retaining the receptacle cover in open position, whereby (when in such position) the cover may be utilised as a rack. John Henry Rubenking, Jr., Barton view, State Illinois, U.S.A.

## New Trade Names.

**WINGED SHIP (DEVICE).**—No. 302,236. Chemical substances used in manufactures, photography or philosophical research, and anti-corrosives, but not including glycerine, jellies, oils, or greases, or any goods of a like description. Paul Ruben, 56, Leadenhall Street, London, E.C., general merchant. April 13, 1908.

**GLADIATOR.**—No. 306,269. Photographic dry plates and sensitised films. Mawson and Swan, Ltd., Mawson's Buildings, Mosley Street, Newcastle-on-Tyne, Northumberland, chemists and scientific instrument makers. September 17, 1908.

### Strong Prints from Weak Negatives.

Mr. A. H. Hall, writing on this subject to "The Amateur Photographer and Photographic News" for December 1, says: "The easiest method, to my mind, is to make a weak gaslight print, i.e., give an exposure that is too short to obtain full density, but long enough to give full detail without veiling, and to intensify by the well-known bichromate method, followed by re-development with amidol. For the development of the print, in the first case I much prefer well-restrained pyro soda. Development will be somewhat slow, and unless the negative is quite abnormally thin, full density can often be obtained without any further manipulation. The print may be of a pleasing sepia, but is more likely to be a most unpleasant greenish black. It is, therefore, better to stop development before full density is obtained, and intensify as suggested above, when the resulting print will be found to be a pleasing black. A method that gives even finer results, but is rather more trouble, is to make a weak print, harden it, and make an ozobrome on top of the image so formed. The print should then be dried, and when dry, the underlying image can be re-developed with amidol or toned in the sulphide bath. Very fine results can be obtained by this means; in fact, some of the best prints I have been made from a bromide that has inadvertently been under-exposed, with an ozobrome print superposed. A sepia bromide on a print that has been re-developed with amidol gives a very fine warm black. The secret of both these methods is to get a print in the first place that has no signs of veiling, yet is as strong as possible. This entails several trials to get the exact exposure, but the results are certainly worth the trouble involved."

### Christmas Mottoes on Photographic Christmas Cards.

A writer in "Photography and Focus," for December 1 gives the following hints for printing suitable "greetings" on photographic cards. "In most cases it is best to print whatever inscription is required in white letters, and one of the easiest ways of doing this is the following:—Some old celluloid film is obtained, and the gelatine coating is cleaned off it with water and washing soda. Hot water must not be used, as it cockles the film. When quite clean, one side of the film is roughened with some very fine emery powder, and it will then be found that it can be written upon without the ink running. The celluloid film bearing the motto is next fastened in position on the negative with a piece of stamp-paper, the writing being next the film of the negative. The Christmas card can then be printed in the usual way, and the lettering will show up plainly upon it in white. It is advisable to use Indian ink for writing on the film, as this will be found to dry very much blacker than ordinary writing fluid. The edge of the film may sometimes show in the finished print, but this can generally be avoided by trimming the film so that the edge of the celluloid follows some lines in the picture, such as the side of the road, the top of a wall, or some similar detail.

With some subjects, such as snow scenes, for example, the lettering has to appear darker than the rest of the picture. This is rather more troublesome, but does not present any great difficulties. To do it we proceed to write the wording on a smooth sheet of white paper, or if this is beyond the ability of the photographer he can get his stationer to have it printed. This is then photographed in a good light, and so gives us an opaque negative with the words transparent. The picture is printed in the usual way, and the print is then placed under the negative of the lettering, which is then in its turn printed. The words soon appear clearly in dark lettering, while the rest of the print is protected by the black negative."

**PHOTOGRAPHER'S STOCK RAIDED.**—Some persons, bent on theft as well as wilful destruction, forced an entrance to the shop of Mr. Joseph A. Hall, photographer, of Holmside, Sunderland, one night last week. They did not content themselves with stealing goods worth about £10, but did damage in addition by smashing plates and other articles to the amount of about £30.

## Dew Apparatus, &c.

The "Ensign" Lantern Screen. Made by Houghtons Ltd., 88 and 89, High Holborn, W.C.

A very ingenious and convenient form of lantern screen, suitable for pictures projected to a moderate size, is being introduced by Messrs. Houghtons, under their general trade name of "Ensign." The two drawings explain the construction and mode of action of the screen. The baseboard is formed by the box, which is caused to stand steadily by the two feet seen in Fig. 1, which feet are turned in flush with the box when the screen is being put away, as shown in

Fig. 1.

Fig. 2. The supporting frame contains two vertical supports hinged about half-way along their length, and each connected with the top piece, which carries the screen. This latter is attached to a spring roller, and is operated in the way customary with this domestic accessory. The erection of the framework is the work of a second or two, and calls for no standing on chairs or reaching to the top of the

Fig. 2.

frame. All that is necessary is to raise the side pieces and press the locking struts into position. The screen is thus a most convenient one for schoolrooms, home use, or wherever a 4ft. or 6ft. picture is large enough. In sizes for these two discs the apparatus costs 32s. 6d. and 42s. respectively, complete with frame, case, and screen.

The Westminster No. 1 Printing Frame for Arc Light. Made by the Westminster Engineering Co., Ltd., Victoria Road, Willesden Junction, N.W.

The form which this apparatus takes is clearly shown in the accompanying drawing from which it will be seen that printing frames are placed round the shaded arc lamp in two rows, the upper frames being placed upon a narrow shelf whilst the lower

ones rest on the floor of the apparatus. The depth of the apparatus, 2ft. 2in., allows of frames of the largest size being employed, whilst as many as 70 half-plate frames can be accommo-

dated. The apparatus is mounted on a ball-bearing centre, which permits of it being rotated by a touch of the hand, any frame being thus instantly got at, and the intermittent rotation of the apparatus further equalising the light. Two distinctive good features of the apparatus are that the frames are put in without requiring to be attached in any way, and that the operator is never exposed to a glare of bright light, the broad shade over the arc cutting off direct rays from the latter, and allowing of the papers being examined without fear of veiling the sensitive surface, and further without so dazzling the printer's eyes that he is unable to judge of fine detail in, say, a platinotype print. The price of the apparatus complete with light shield is £4 10s.

## New Books.

"Deutscher Camera Almanach," 1909. Berlin: Gustav Schmidt. M4.

Since the commencement of the preparation of this volume for the press, the death of Herr Fritz Loescher, the editor, has taken place, and the completion of this work has thus been in other hands, those of Herr Otto Ewel. Still, the volume is produced on the lines of its four predecessors. It includes a large number of reproductions of German, French, and British examples of current pictorial work, accompanied not by criticisms thereof (for this relief much thanks: one can easily have too much of the art critic's comments), but by contributed articles upon topics which are about equally divided between the æsthetic and technical aspects of photography. Where illustration is so ample there must necessarily be a good sprinkling of the ordinary, but one or two reproductions of notable merit are the beautiful landscape of Ledenig (we hope this worker will be represented in the next R.P.S. Exhibition), Mr. E. O. Hoppé's portrait of Maud Allan, M. Demachy's "Trouville," and a delightful bit of landscape by M. Vanderkindere. Of the articles, that of perhaps chief interest is M. Demachy's on the oil process. The work of the photo-engraver and printer has been admirably done, and though the shiny "art" paper is rather distracting, no contributor can complain that his original has not been perfectly "brought up."

"Deutscher Photographen Kalender," 1909. Part II. Weim Office of "Deutscher Photographen Zeitung. M2.

This second part of the compact and useful calendar of Herr I. Schwier contains, as usual, a diary for 1909 and the compendium tables and codified facts relating to photography, and comp chiefly for the use of German-speaking photographers. The last portion consists of a formulary of photographic processes from collodion, dry-plate methods, including orthochromatics, through positive printing processes to miscellaneous recipes and prescriptions. The inclusion of catatype, ozobrome, and carbograph is an instance of the revision which has taken place in these portions of "Kalender." Also, we now see a number of formulæ for the sepia or sepia toning of bromide prints and other evidences of Herr Schwier's publication being kept abreast of current progress.

"The American Annual of Photography." Edited by John Tennant. London, Dawbarn and Ward, Ltd., 6, Farring Avenue, E.C. 3s. net.

The text portion of this handsomely printed volume is ably equally divided between a number of contributed articles and reproductions of photographs which, in the majority of cases, evidently have a pictorial aim. A good many workers well known in European circles are here represented, as also some very interesting work of some of the American professionals, such as Herr Hall and Charles H. Davis. The contributions mostly assume the character of articles on practical expedients and methods relating to commercial and professional photography almost as much as the camera as an amateur pursuit. There is a directory of American photographic societies, and a brief, but useful, formulary of recipes for developers, printing processes, etc.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

#### FRIDAY, DECEMBER 4.

Sutton Photographic Club. "Printing on Bromide Papers." Andrew Pringle.  
Mill Camera Club. "Photographic Chemical Experiments." E. Cooper.  
Aberdeen Photo Art Club. "The Decorative Element." J. A. H. Hector.  
Bury Athenæum Amateur Photographic Society, Bury. Dutch Lantern Pictures.  
A. E. Staley & Co.  
L.C.C. School of Photo-Engraving, Bolt Court. "Max Levy Etching Machine."  
W. Gamble.  
Lancaster Photographic Society. Competition Lantern Slides.

#### SATURDAY, DECEMBER 5.

St. Helens Camera Club. "On the Printing, Developing, and Toning of Velox Papers." W. F. Slater.

#### MONDAY, DECEMBER 7.

Scarborough and District Photographic Society. Photography Prize Slides.  
South London Photographic Society. Lecturette Competition.  
Kidderminster and District Photographic Society. "A.P." Prize Slides.  
Bradford Photographic Society. "Large Bromide Prints from small Negative."  
A. Braeewell.  
Stafford Photographic Society. "Carbon Printing and Ozobrome." W. Leonard Hey.  
Cripplegate Photographic Society. "The Bromoil Process." F. J. Mortimer.  
F.R.P.S.  
Southampton Camera Club. Affiliation Lecture.  
Lancaster Photographic Society. "Glimpses of Wales as seen through a Camera."

 Toning of Velox Papers." W. F. Slater.

BIRMINGHAM PHOTOGRAPHIC SOCIETY. — On Tuesday evening, November 24, a lecture, entitled "The Land of Canals, Carillons, and Coifs," was given by Mr. C. B. Howdill, of Leeds, before a good audience, Mr. Harold Baker in the chair. The lecture opened with a short historical sketch of the Netherlands, then commencing on his journey Mr. Howdill led his audience via Dover-Ostend to Bruges, where he explained that the carillons in the church towers give out their chimes every 7½ minutes and play a complete tune every hour; on to Brussels, which boasts the finest municipal buildings in the world, where he was fortunate enough to witness the bicentenary procession to commemorate the rebuilding of the Guild-houses; travelling northward to Antwerp, where the tower of Notre Dame contains a carillon of ninety-nine bells. From here he visited The Hague, Leyden, Haarlem and Alkmaar, all of which suffered severely during the Spanish wars, thence by canal to Amsterdam and Marken, and home via the Hook of Holland. The lecture was interspersed by ray stories, and was of considerable topical interest. A series of slides illustrating the coifs or head-dresses of various parts of the country being a particular feature; and several slides by the Sanger-Shepherd process of pictures by Jan Steer, Teniers, and Rembrandt, which Mr. Howdill had obtained permission to photograph in the Ryks Museum at Amsterdam, were well received.

## Commercial & Legal Intelligence.

LEGAL NOTICES.—A first and final dividend of 2s. 3d. in the £ is to be paid on December 10 in the case of Ralph Winter Thomas, photographic dealer, residing at 28, Burghley Road, St. Andrew's Park, Bristol, and carrying on business at 69, Stokes-croft, Bristol.

ARTISTIC "GUILDS" AND "ASSOCIATIONS."—At Hereford last week, Jack Davies, photographer, Gothic Cottage, Widemarsh Street, was charged on adjournment with being the bailee of a certain picture of the value of 15s., the property of Virginia Large, Stanhope Street, and unlawfully and fraudulently converting the same to his own use on October 29. He was also charged with, being the bailee of a certain picture, value 10s. 6d., the property of Miss Frances Evans, Chandos Street, which he did unlawfully and fraudulently convert to his own use on October 21.

Mr. W. M. Akerman prosecuted for the police, and Mr. E. A. Capel defended.

Evidence was given by Mrs. Virginia Large to the effect that defendant came to her house one day in October last and asked her to lend a picture he had previously enlarged for her. She first of all saw the defendant's wife about September 1. Witness subsequently handed her a photograph which was enlarged. She gave the order on September 9, and the defendant asked for half the amount of the cost, which was 7s. She handed this amount to him, and subsequently paid him 14s., and 1s. extra for another mount. The defendant called again with reference to some midgets, and she paid half of the account. On October 19 the defendant borrowed the picture he enlarged and the frame, telling her that he desired to show it to a lady at Burghill. He promised to bring it back on the next day. On the following day she received a postcard from him. It was addressed: "Art Company, Gothic Cottage, Widemarsh Street," and signed "J. Davies," and it purported to explain a delay in not returning the frame. On the 22nd she had another postcard, asking her to excuse the return of the frame until a further date. She sub-

sequently saw the defendant's wife on the 24th, and she said the defendant was out with the picture, having gone into the country. On the 26th she received a letter from him promising to return the photograph later on, and to make her the present of an extra photograph for keeping her so long. The defendant's wife subsequently showed her the picture without frame or glass. She said her husband had not come back from Manchester. Mrs. Davies afterwards said she would see that the frame was all right. Witness paid subsequent visits to Gothic Cottage, and found the Davies' had gone. She applied for a warrant on November 9. Afterwards she received a postcard from Cinderford signed "E. Davies."

The prisoner said he was at present living at Cinderford. When he first went to Gothic Cottage, Hereford, he worked for his brother. His brother left about five weeks afterwards, and he (defendant) continued to work at Hereford on his own account. He borrowed Mrs. Large's framed photograph to show to customers, and admitted saying he would return it, but he broke the glass and damaged the frame. He then took the frame off the picture and used it for another because he was short of money at the time. He meant to replace the frame. He got his frames from Manchester. He had no intention of robbing Mrs. Large or anyone else. He was absolutely broke, and he wrote to his brother, who came to an arrangement to finish and deliver the pictures that were there as soon as he had the chance. Amongst the pictures was Mrs. Large's. He endeavoured to get work in London, but did not succeed, and then returned to his brother. They could not get a further supply of frames in time owing to the removal of a firm in Manchester. His brother had executed several of the orders since his arrest, and the others would have been completed only the photographs were in the possession of the police.

Cross-examined: Mrs. Large's frame was now at Holme Lacy, having been supplied to a customer there. He was not in partnership with his brother. His brother's firm was "The American Artistic Guild." He was his brother's servant. He was three years older than his brother. His brother's banking account was at the United Counties' Bank, Broad Street, Hereford. He (prisoner) came from Manchester to Hereford. He either called himself "H." or "J." Davies. At Manchester he worked for the Apollo Art Association. There were no complaints about his business in Kendal. There were no complaints in Hereford about frames. With regard to Mrs. Large's frame, he had been paid for it twice over. He admitted using several of his customers' frames, but he intended to replace them. He had had about twenty frames from Manchester.

Prisoner denied convictions at Manchester in the name of Louis Beerbohm. He had a brother living at 6, Pembroke Street, Manchester.

Izidore Davies said he was known as Izzy Davies. He left Hereford because he wanted to work by himself. He went to Ross. He received a communication from his brother's wife, and accordingly went to Hereford. His brother then explained his position, and asked him to help him. He promised to meet the demands of the customers. He immediately started to complete the orders. He bought some frames at Bristol, and intended to frame the remaining photographs, but the police had in the meantime taken them away. He produced acknowledgments purporting to show that he had completed some of his brother's orders. As soon as he got the photographs in court in his possession he would complete the orders. Mrs. Large could have the frame produced in court.

Cross-examined: He bought the frame produced in order to accommodate his brother, and meet Mrs. Large's demands. The business was his. He did not have studios at Chicago, Manchester, Edinburgh, Carlisle and Lancaster. It was a matter of form to state so on his circular issued from the Merton Hotel, Hereford. An enlargement of Mrs. Rudge, of Ledbury Road, would be delivered when she paid the balance. She had paid half the amount, 6s. 6d. He would not execute the order until the other half had been paid, because he had been "had" by other people.

The Chairman said the Bench had carefully considered the case, and were quite satisfied that the defendant fraudulently converted the frame to the use of some person other than the owner, and, consequently, was guilty of larceny within the meaning of the Act.

The Chairman said he was sorry to see a young man like defendant in court on such a serious charge, and he would be fined £15, or two months' imprisonment with hard labour.

LUXIA COMPANY. —In the Chancery Division recently, before Mr.

Justice Eve, the action of *Berger v. Turtle* was heard. Mr. Ward Coldridge said this was a motion by plaintiff (Mr. Maurice S. Berger) for the appointment of a receiver of a business carried on in partnership by plaintiff and defendant as manufacturers of sensitised paper called "Luxia." The parties had got along for some years amicably, plaintiff attending to the technical part of the business until quite recently. In 1906 there was a suggestion by defendant that the business should be sold, and a written agreement was entered into, under which plaintiff was to have a share of the proceeds of sale. Plaintiff was described in that agreement as manager, and apparently defendant thought he could get rid of his partner now by merely giving him notice. Plaintiff then issued a writ claiming the usual relief in an action for dissolution of partnership. In his affidavit plaintiff stated that he founded the business in conjunction with defendant, who was his father-in-law, and they entered into a verbal agreement of partnership on the terms that they should trade as the Luxia Company. The name "Luxia" was invented by plaintiff to describe certain formulæ which plaintiff alone understood.

The defendant, who appeared in person, said he denied most emphatically that he ever entered into an agreement of partnership with the plaintiff. Plaintiff relied on the agreement of April 9, 1906, as constituting the partnership, but that was not an agreement of partnership, and was never intended by either party as such. A one-third share was distinctly stated to be given to the plaintiff as bonus, and no partner received bonuses. The business was absolutely his (defendant's), as he bought it from trustees. Plaintiff was also claiming salary due to him as manager from him (defendant), and he could have dismissed plaintiff with a month's notice at any time. The agreement in question was entered into two days before he underwent a serious operation simply that he might get the formulæ which plaintiff had always refused to give, saying they were incomplete, and he (defendant) had to employ a chemist to complete them. Plaintiff had acted treacherously by going to his (defendant's) largest creditors saying he was selling the business to a limited company. Plaintiff had never put one penny into the business, and he (defendant) had lost £8,000 from first to last in trying to find this son-in-law employment.

His Lordship remarked to Mr. Coldridge that he felt a difficulty because the agreement mentioned on the writ was certainly not a partnership agreement. Mr. Coldridge said the contention of the defendant was absurd. He said he obtained these valuable formulæ, without which the business was useless, merely by appointing his son-in-law manager, with power to dismiss him next day.

In the result his Lordship said he would let the motion stand over until Friday week, with leave to the plaintiff to amend the writ and notice of motion, and Mr. Turtle must be prepared, if he denied the existence of a partnership, with an affidavit to that effect.

On November 20 Mr. Coldridge said he had to renew the application he made on the previous Friday for the appointment of a receiver and manager of the business carried on by the parties in partnership as the Luxia Company, makers of sensitised paper.

Without calling on the defendant, who appeared in person, his Lordship gave judgment. He said he understood that defendant was the father-in-law of the plaintiff. Defendant had strenuously denied that there was any partnership, and it was quite obvious to him on the evidence filed that the plaintiff had not in his affidavit in reply dealt with the only material paragraph in the affidavit of the defendant that there never existed any verbal partnership. Under these circumstances, and holding that the agreement exhibited negatived the existence of any such relationship, he had no alternative but to dismiss the motion with costs.

Defendant said plaintiff was retaining the keys of his safe and premises.

His Lordship said he could make no order for the return of the keys on that occasion. He could only intimate that the plaintiff had no right to retain the keys. Motion refused, with costs.

**PHOTO-FRAME DISPUTE.**—In the City of London Court, on November 24, before Judge Rentoul, K.C., and a jury, an action was brought by Mr. Hans L. Zinck, manufacturer of photo frames, Mühlberg-in-Thüringen, against S. Hildesheimer and Co., Ltd., photographic dealers, 96, Clerkenwell Road, to recover the sum of £74 1s. 4d. for photo frames supplied. Mr. L. Tyfield and Mr. A. Bryan appeared for the plaintiff, and Mr. Given and Mr. Gervase

Rentoul for the defendants. Plaintiff's case was that his representative in England, Mr. Abrahams, 54, Redcross Street, Finsbury, was anxious to obtain orders for photo frames from the defendants. Abrahams endeavoured to induce the defendants' manager of the photo-frame department to come and see his samples. Mr. O. F. Hoffmann, the defendants' manager, called, and, after an inspection, he gave an order for £82 9s. 6d. worth of photo frames, which included 100 samples to send out to the travellers who were to take the order. All the goods had to be made specially for the defendants. Abrahams' principals in Germany. A portion of the goods had been sent, Messrs. Abrahams received a letter from Mr. S. Hoffmann, the defendants' manager, saying that he did not see sufficient profit in the frames, and that Pym had no business to have given the order, which was only conditional on Sonn's approval, and that was not given. Pym had asked Abrahams to hold the goods over, and plaintiff came to the conclusion that the defendants were making a loss, they were asked to pay for the goods which had been ordered in the general way. Plaintiff's agent did not take the order subject to any confirmation, but it was an out-and-out sale. Four months after the order had been given the defendants declined to accept the goods, and the present action was brought. Mr. Abrahams' explanation, said he was paid on commission; but it had not been paid in the present transaction. He would not have accepted the order if it was subject to a confirmation. He did not say he would try to sell the goods elsewhere to save getting into trouble with his firm. For the defence, Mr. Oscar Pym was called, and said he never gave any definite order. He had no power to do so without his manager's confirmation, and that was never done. Sonn's sanction was never given to the goods being received, and therefore had to be refused. Mr. Edward Sonn said no order was confirmed by him in the matter, except for samples which they paid for. There was a clause on their order forms stating that no order was valid unless it was in writing and countersigned by himself, the secretary of the company. That had never been done in the plaintiff's case. The jury found that the defendants gave the order. Judge Rentoul said that there was no evidence of damage, and he could award the plaintiffs was £d. and costs.

**EASTMAN KODAK COMPANY OF NEW JERSEY.**—The usual quarterly dividends of 1½ per cent. (being at the rate of 6 per cent. per annum) upon the outstanding preferred stock, and of 2½ per cent. (being at the rate of 10 per cent. per annum) upon the outstanding common stock of the Eastman Kodak Company of New Jersey, to be paid on January 1, 1909, to stockholders of record on November 30, 1908.

**A CHATEAU BANKRUPTCY.**—The first meeting of the creditors of William Beard, 78, Canterbury Street, Gillingham, near Chatham, photographer, formerly of 113, High Street, Gillingham, and of Brompton, took place on Monday at the Official Receiver's Office, Rochester. The statement of affairs showed gross liabilities £4s. 6d., of which £44 was given as partially secured by bill of sale on the debtor's furniture at his last address. The debtor filed his own petition, and at the time the county court were in possession of his effects under a warrant of execution issued by creditors. The deficiency is stated to be £689 6s. 6d., as, apart from the goods on which the bill of sale was given, the debtor has no effects. He began business in March of 1897 at High Street, Gillingham, in partnership with a Mr. Harry Hill. This partnership was dissolved in March, 1898, and debtor carried on the same business in his own name. After this he appears to have taken another partner, Mr. Thomas, and traded in coals. This partnership has, however, been dissolved, as from March, 1905. At the public examination (at Rochester County Court) in the afternoon of the same day, the debtor stated (in answer to Mr. R. O. Tatham, the Official Receiver) that he was unable to tell his financial position at any time from the books he had kept, as the ledger only recorded what was owed to him and not what he owed to his creditors. He was overdrawn at the London and Provincial Bank to the amount of £245, but this was guaranteed by a Mr. Thomas, and he, in turn, was guaranteed by the debtor's wife in respect of a reversionary interest due on mortgages, and due to the wife upon the death of her mother. Mr. Thomas, a former partner, had also advanced him £250 in various sums from time to time, and he had used the money in the payment of debts. The debtor (who was represented by Mr. W. A. Watts, solicitor, Chatham) was allowed to pass, upon signing notes. There were no creditors present to oppose him.

**FRAUD BY CANVASSERS.**—Last week, at Broxburn, near Edinburgh, two men named John Paul and William Davidson Gray, canvassers, 100, Victoria Street, Bathgate, were charged with pretending to various people that one of them, Gray, was collector for Mr. John McLaren, photographer, Broxburn, and thus induced people to deliver to them various sums of money, which they appropriated to their own use, on Wednesday, November 11. Paul did not put in an appearance, and a warrant was issued for his apprehension. Gray pleaded guilty to the charge. The Fiscal stated that Paul had really been employed by Mr. McLaren, Broxburn, to take orders, but had no authority to collect money. He first called on these people and got their orders, and some time later on brought round Gray, whom he represented as McLaren's collector. As already stated, he induced people to hand over sums of money. Gray was not in McLaren's employment at all. Judge Grieve characterised the fraud as a most contemptible one, and said that the community must be protected from such men as Gray. The penalty would be ten days' imprisonment, without the option of a fine.

#### NEW COMPANIES.

**A. DUGGLEBY, LTD.**—Registered November 10. Capital £1,000, in £1 shares. Objects: To take over the business of a chemist, druggist, dealer in patent medicines, drugs, optical and photographic requisites, carried on by Albert Duggleby at 81, Leigh Road, West Cliff-on-Sea, as Duggleby's Drug Stores. Private company. Registered office, 81, Leigh Road, West Cliff-on-Sea.

## News and Notes.

**THE R.P.S. DINNER.**—The annual dinner of the Royal Photographic Society took place at the Holborn Restaurant on Tuesday last, the president, Mr. J. C. S. Mummery, presiding. The usual royal toasts were given and responded to with enthusiasm. Lord Redesdale proposed success to the society specially coupling with it the name of the president. Mr. Mummery in responding said that he had no intention of giving on that occasion any detailed account of the annual report, but touched a little upon the work of the society and the recent exhibition, which, notwithstanding the counter attraction of the Franco-British exhibition had proved a complete success. The musical arrangements, which were under the direction of Messrs. Furley Lewis and A. W. W. Bartlett, were much appreciated by all present, and the company did not disperse until a late hour.

**GLASGOW SOUTHERN PHOTOGRAPHIC ASSOCIATION.**—At the annual exhibition of the above society, to be held in the Club Rooms, Eglinton Street, from January 19 to 30, 1909, there will be three competitive classes open to all photographers, one of which will be specially devoted to colour photography. Messrs. Archibald Cochrane and E. Christie have consented to act as judges, and bronze plaques will be placed at their disposal for award. There will also be several special awards, including a silver plaque for the picture which in the judge's opinion is the best sent in for competition. Entries close December 30, 1908, on or before which date all entry forms, accompanied by entry fees, must reach the hon. secretary, Mr. R. Lindsay, 88, Eglinton Street, Glasgow, S.S. Mr. Lindsay will also be pleased to supply any further information, together with entry forms, to those applying for same.

**COUNCILLOR G. E. HOUGHTON.**—At the bye-election for the filling of vacancies upon the Margate Town Council last week, Mr. G. E. Houghton was elected a member of the Council for the forthcoming year.

**DEATH OF HERR W. KNAPP.**—We regret to hear of the death, on November 24, of Herr W. Knapp, for many years head of the well-known firm of technical publishers bearing his name. Herr Knapp occupied a unique position as a photographic publisher, for from his press at Halle a whole series of photographic periodical and other publications emanated, and he was widely known and respected in photographic circles.

**WEST HAM EDUCATION COMMITTEE,** at their meeting on Monday, agreed to place an order with Messrs. W. Tylor, Ltd., to supply 10,000 lantern slides per annum each to Holbrook Road and Star Lane schools for the purpose of illustrating certain lessons, at 25 s. per school, on condition that the slides are to be retained at the schools for a period not exceeding forty-eight hours.

#### CARD-FILING FOR STUDIO BUSINESS.

To the Editors.

Gentlemen, We have read with interest Mr. Foster Brigham's article on "The Card-Filing System for Professional Portrait Business," and we would venture to suggest that we have been advocating this method of keeping studio accounts, registering appointments and progress of work, for some time past. We have had on sale for over a year cabinets and outfits with the cards ruled and subdivided in a complete and yet essentially simple manner. These printed cards are more easy to keep posted than the written cards illustrated by Mr. Brigham, and they have the advantage of always keeping the same kind of information in the same place. Notes about conversation with the receptionist and the sitter's predilection for certain styles are relegated to the back of the card, as also are memoranda about the dress of the sitter and the whereabouts of the filed negatives.

You were good enough to draw attention to this filing system last year, and you may now be agreeable to reminding your readers of it again, in view of the interest that is certain to be provoked by Mr. Brigham's eminently practical article.—Yours faithfully,

HOUGHTONS, LTD.

[We are glad to accede to Messrs. Houghtons' request, particularly so as we believe the arrangement of their special card was produced from one of Mr. Pirie Macdonald's, described in the "British Journal." Messrs. Houghtons, Ltd., have, however, produced a card to meet British requirements. We describe it and the outfit on page 927.—Eds. "B.J.P."]

## Answers to Correspondents.

#### PHOTOGRAPHS REGISTERED:—

- R. T. Ford, 125, King Street, Cheshire. *Two Photographs of the late Rev. Father Wm. F. Stanley, late Rector of St. Peter and Paul's, New Brighton, Cheshire.*  
 Two Photographs of the Right Rev. H. Singleton, D.D., Bishop of Shrewsbury.  
 Two Photographs of the late Right Rev. S. W. Allen, D.D., late Bishop of Hereford.
- J. H. Begg, Junr., 15, Albion Terrace, Aberdeen. *Photograph of a Dog.*  
 P. D. Prior, Milton Chambers, Milton Street, Nottingham. *Photograph of Double Nest made by One Pair of Greenfinches.*  
 J. Mills, 11, Gold Street, Northampton. *Four Photographs of Miss Ellen Terry (Mrs. James Carew).*  
 W. A. Mallett, Church Street, Tewkesbury, Gloucestershire. *Photograph entitled: "Sunset on the Lordly Severn, Tewkesbury."*  
 B. Griffin, 29, High West Street, Dorchester, Dorset. *Two Photographs of Thomas Hardy.*  
 W. Whiffin, 237, East India Dock Road, Poplar, E. *Photograph (Combination) of a player's Ground of the Millwall Football Club, 1908-9.*  
 A. Dimberline, 3, Mission Street, Marsh, Huddersfield. *Two Photographs of Miss Annie Graham, Missionary from China.*

**JOHN HUTCHESON.**—(1) The number of the patent specification is 17,007, of 1905. An abstract appeared in our issue of June 29, 1906, and in the "British Journal Almanac," 1907, p. 803. (2) There are no patents now in force as to the making of ordinary carbon tissue.

**PHOTOGRAPHY AS PROFESSION.**—Having been a good many years an amateur photographer, and my daughter being nearly fifteen, would you kindly say what chances there are in putting her to learn the business, with a view of setting up at it; what is the best way for me to proceed to get her apprenticed or otherwise, and how many years, etc.? Any information will be greatly esteemed.—W. WALL.

If your daughter has both natural aptitude for portrait photography and also business instinct, there may be a good prospect of her doing well in business for herself. But for assistants there are not very bright prospects at present, the market being overstocked with labour. The best course of training would be to apprentice your daughter to a good firm, but before doing so we advise you to study the pages of the "B.J.," wherein you will find the advertisements of situations wanted and vacant. In the event of your contemplating a definite step we would be willing to give you an interview, when we might be able to give you some advice.

**LENS FOR PORTRAITURE.**—What lens would you advise for home portrait work? I require a quick lens for children. I have obtained good results with 1.1 (rectilinear) lens for cabinet heads and smaller sizes, but I require something quicker to use with  $\frac{1}{2}$ -plate cameras. —ARTIST.

The quickest lens you can have for portraits is a portrait lens. These may be had with an aperture of about  $f/5$ . A good cabinet lens of from 11in. to 12in. focus will cover the half-plate very well; indeed, a larger size if stopped down.

**COLLODION PRINTS.**—We should be very much obliged to you if you would kindly help us to find out the cause of the yellow stains. We wash prints well before toning, then tone in borax gold bath, then wash again in, say, six changes of water, and put them in platinum bath. After this we wash them well again and fix them for fifteen minutes. After this we wash them by hand, changing them for two hours, say, every five to ten minutes, and put them to dry between clean, pure blotting-paper. In the last week or two we have been troubled by these yellow stains, which occur, say, in four or five prints out of a batch of sixty, and occur about a week or so after they are mounted. Would the cause of it be the mounts? We send you a few for inspection. You will notice little yellow marks on them, or is it the fault of our printer or in the mounting? —STAINS (Wales).

Yellow spots, such as those on the prints, are sometimes caused by too slow drying of prints, which have been mounted. It is possible that the mounts may be, to some extent, at fault, but quick drying in a quite warm room will perhaps be the means of avoiding your present trouble. We would refer you to the "B.J. Almanac," for 1907 for a series of articles on the numerous points which call for attention in working collodion paper.

**DEVELOPER.**—I have to thank you for your prompt reply to my question in your last issue re developer. I may say I have taken your advice, and with satisfaction. Having exposed some plates under bad circumstances as to light, some were developed with pyro-soda and the others with pyro-metol. There was no image whatever with the former after developing twenty-five minutes, but with the pyro-metol I obtained a fair image on the plate, all being exposed at the same time and place. If I am not troubling you too much might I ask which developer you consider best for seascapes and children's portraits outside, dressed in white? Is metol the best? —LONG READER.

We should not consider the particular developer of very material importance. The chief point, especially with light-toned subjects, such as children in light dresses, is not to over-exposure nor to over-develop. Keep the negative thin, and, as metol tends to a thin negative, you will not go far wrong with it.

**MISS WALKER.**—Perhaps if you apply to Mr. F. A. Bridge, East Lodge, Dalston, N.E., he may be able to help you.

**HARRY WATSON.**—(1) Apply to Fallowfield, 146, Charing Cross Road, London, W.; or Billcliff's Camera Works, Manchester, S.W. (2) The Tress Company, 4, Rathbone Place, London, W.

**D. Y., M. R. L., and others.**—We will reply next week.

**CARBONERA.**—You require to register the transference of the copyright at Stationers' Hall, on the form provided for the purpose.

**PYRO.**—We have no information as to working formulae, which are largely trade secrets. A formula for rapid bromide P.O.P. emulsion was published by Valenta last year. See the "Almanac," 1908, p. 641; but such paper, or any chloro-citrate paper, cannot be developed with an alkaline developer.

**REDUCING OVERPRINTED PLATINOTYPES.**—Will you be so kind to advise me of the formula for the reduction of overprinted platinotypes? The same may be reduced if treated before the final acid bath, I believe, not when dry. I have an idea it is chloride of platinum, but of this I cannot be sure. I have tried chloroplatinate, but of no avail. —PLATINOTYPE.

If prints be placed for about two minutes in the oxalate developer, then for about 1 second in 1:20 hydrochloric acid, and then put back again in the developer and treated as usual, some reduction of the effect of overprinting is obtained. The only reagent for the finished print is a weak solution of chlorine water.

**R. T.—1.** We can only suggest that you offer the prints to the leading postcard publishers. 2. Negative intensified by the

mercury iodide method followed by re-development should be quite permanent. It is not correct to assume that a mercury process necessarily gives impermanent results. Mercury followed by ferrous oxalate developer gives quite permanent intensification.

**RETOUCHER.**—What you complain of is certainly illegal, and it is evident that you know how to put a stop to it in your case, namely by bringing the facts to the notice of the local Factory Inspector. You can, of course, do that. It is not at all unusual for employees to be called to work somewhat longer hours during the pre-Christmas work, and that they very generally do cheerfully. Usually the employer makes some recompense for this in the shape of extra pay, presents, or Christmas boxes. The hardship is not so very great, after all.

**GREEN TONES ON BROMIDES.**—Can you oblige me with a good reliable formula for the toning of bromides a sea-green colour? I have an idea I have seen such. —SEA-GREEN.

One is given in the "Almanac," page 810, but this and other formulae are not perfectly satisfactory. The Leto Company supply a better preparation for green tones.

**TOE THE LINE.**—It is not usually held to do so. An amateur is commonly regarded as one who does not rely upon his hobby as a means of livelihood.

**INQUIRER.**—We can only generally tell you that conditions in Australia are very much as here. The two papers are the "Australian Photo-Review," 375, George Street, Sydney, and the "Australian Photo-Journal," 386, George Street, Sydney.

**COPYRIGHT.**—I take the liberty of writing you about a subject which is rather troublesome to an outsider, viz., I have a photograph which I bought. It has seemingly been reproduced from an oil painting done in 1886. Now what I want to know is this: if I am at liberty to copy this photograph for illustrating a catalogue. The gravure has no indications of being copyrighted. The catalogue, of course, will not be sold. —POLAR STAR.

It is immaterial whether your reproduction will appear in a publication which is to be sold or distributed free. If there is copyright on the engraving—and very probably there is—you have no right to make or publish a copy. It is not necessary that the word "copyright" should appear on a work in which there is copyright.

**FACTORY ACT.**—Will you please tell me through your paper if it is illegal to have a female employed in the reception room on Sunday, if she has the time allowed off during the week, and would it make any difference if she were manageress? The factory inspector called here to warn us about the same, and said that we should take proceedings if we continued to have a female receptionist on Sunday. This is rather an important question as it will affect photographers all over the country. —FACTORY INSPECTOR.

Under the Factory Act it is illegal to employ females on the Sunday in any workshop. If the receptionist is engaged in any work, such as mounting, spotting, retouching, etc., she comes in with the other workers as a workwoman under the Act, and it is illegal to employ her on the Sunday, even if she has time off during the week. The factory inspector, no doubt, knows the conditions under which she is employed better than we do. Hence his notice.

**NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

The activity being shown both by licensing authorities and by the cinematograph trade in the prevention of fires is evident from the report printed on page 945.

A demonstration of the new Lumière non-flammable film was given on Tuesday last. (P. 953.)

The president of the R.P.S. in his annual address dwelt upon the destroying effect which photography had had upon a number of the more minor arts. (P. 949.)

We suggest to photographic societies holding members' exhibitions the systematic restriction from competition of members who have taken, say, four awards. (P. 938.)

At the ordinary general meeting of Ilford, Ltd., held last week, the report recorded considerably increased sales (despite keen competition) and a large increase in the profit on trading account. (P. 945.)

A new printing paper of quite distinct properties and with many attractive features has just been placed upon the market. (P. 951.)

We suggest the construction of a stereoscopic camera in which the act of focussing on near objects would automatically effect a further separation of the two lenses. (P. 937.)

An account of the training now being given in photography to girls by the London County Council is published in the form of an article on page 940.

The first portion of an important paper by Mr. Herbert E. Ives on the Lippmann colour photograph appears on page 942.

Telegraphic transmission of photographs and repairs of cinematograph film figure among patents of the week. (P. 947.)

The conclusion of the miscellany of hints on portraiture appears on page 941.

An analysis of some current formulæ for metol-hydroquinone gas-light developers leads us to a formula which may be taken as a useful working average. (P. 933.)

The advisability of catering for photographs of fair size instead of largely for midget and similar prints may be offered as a suggestion to the middle-class professional photographer. (P. 938.)

## EX CATHEDRA.

### Silver Ferrocyanide in Photographic Processes.

That the properties of ferrocyanide of silver, the chief product of the action of ferricyanide upon a silver image, still contain the basis for photographic processes is shown by two German patents recently granted. In that of A. Tellkamp (No. 201,968 of August 10, 1905) advantage is taken of the bleached silver image to produce a surface from which proofs in greasy ink may be taken. The ferricyanide-bleached print is applied to a gelatine film containing a ferrous salt (prepared from a mixture of 100 gms. of gelatine and 1 gm. of ferrous sulphate in 600 ccs. of water). The unaltered ferricyanide in the print combines with the ferrous salt, producing an insoluble salt in the gelatine, which, after this treatment, is able to absorb a fatty ink. From the relief film thus obtained, prints are taken off by contact. In the case of the second patent (No. 202,108, May 15, 1907, of the Neue Photographische Gesellschaft), the bleached prints are obtained by treatment with a 5 to 10 per cent. solution of potassium ferricyanide. They are then washed and coated with a mixture of pigment and casein. On drying, the whole is treated for ten to fifteen minutes in a solution containing 2 gms. of potassium bromide and 1 gm. of potassium bichromate in 100 ccs. of water, "washed" with warm water, and fixed by means of hypo. The action here seems to be somewhat akin to that in the ozobrome process.

### An Automatic Stereoscopic Camera.

We suggested some time ago that for scientific stereo work a camera with an adjustable front is a necessity in dealing with near objects. If this movement is not supplied, the corresponding images of the principal object move apart as the object comes nearer, and get inconveniently near the ends of the plate, if not off it altogether. Camera makers do not seem to realise that this adjusting front can very readily be made to work automatically as the camera is racked out, with the aid of two guides that will control the separation of a pair of sliding panels. These guides will naturally be curved, and their form can easily be calculated. If properly adjusted, the principal object in view will always be represented in the centre of each of the separate stereo images, so that when using ordinary stereo size plates the maximum separation for distant objects should be  $3\frac{1}{4}$  in. The production of a half full-size image will then require the separation to be reduced by one-third, that is, to about 2 in., which is generally the least separation that can be arranged with lenses of ordinary size. Larger images than this will seldom be required. The rule governing the amount by which the separation must be diminished as the camera is racked out is a very simple one. If the additional

extension of the camera beyond the infinity mark is equal to the focal length multiplied by  $\frac{1}{f}$  then the separation must be reduced by an amount equal to the maximum separation multiplied by  $\frac{1}{f-f_1}$ . That is to say, when making a quarter full size image we must reduce the separation by one-fifth, or when making a one-sixth full size image, we must diminish the separation by one-seventh, which is nearly half an inch if the original separation is  $3\frac{1}{4}$  in. The automatically adjusting front will render mistakes impossible, and greatly diminish the trouble of setting up the camera.

### Gaslight Paper Developers.

Last week we published a summary of the pyro-soda developers to be found in the makers' formulæ of the 1909 "Almanac." We have made a similar study of twelve metol-hydroquinone formulæ advised for use with gaslight papers, and the results are interesting, as they show a remarkable unanimity in some of the ingredients and an equally remarkable discordance in others. In the first place, eight out of the twelve formulæ prescribe 30 grs. of hydroquinone to every 10 oz. of developer, and six agree in advising 7 to 8 grs. of metol in the same quantity, the average of the whole twelve formulæ being  $7\frac{1}{2}$  grs. Two of the formulæ that do not agree with these figures are for rather exceptional papers, therefore their influence on the general average may be disregarded. One of the others is exceptionally dilute, and may be left out on this ground. The opinion of a large majority is therefore distinctly in favour of relative weights of four parts of hydroquinone to one of metol, and of absolute quantities of 3 grs. hydroquinone and  $\frac{3}{4}$  gr. metol per ounce. As regards bromide, five formulæ favour 3 grs. per 10 oz. of developer, while the extreme variations of the rest are from  $\frac{1}{2}$  gr. to 4 grs. The average for the whole is  $2\frac{1}{2}$  grs., the difference between which and 3 grs. is immaterial; we may therefore in this case take the average, which is equivalent to  $\frac{1}{4}$  gr. per ounce. As to the sulphite, there seem to be considerable differences of opinion, as the quantities given vary from 5 grs. to 44 grs. per ounce. The carbonate quantities are, however, still more erratic, as they vary from 5 grs. to 108 grs. per ounce. In four cases the carbonate is equal to the sulphite, and in one it is less, but the majority favour a larger quantity up to six times the quantity of the sulphite. The average quantities for the whole twelve formulæ are 23 grs. sulphite and 41 grs. carbonate per ounce of developer, while if we eliminate the more erratic quantities, the averages are 26 grs. and 38 grs. respectively. It is, of course, a fact that gaslight papers differ greatly in properties, and very likely the differences in the formulæ have some good reason. At the same time, it is well known that one good amidol formula will work well with practically all the papers. Some of the ready-made developers on the market are also apparently effective with all brands of paper, so probably the differences in the makers' formulæ are not absolutely essential. We may deduce from the figures given that a mean formula would contain about eight parts of sulphite and twelve of carbonate to every one part of hydroquinone. This would give the following formulæ:—

Metol	...	...	...	...	$7\frac{1}{2}$ grs.
Soda sulphite	...	...	...	...	240 "
Hydroquinone	...	...	...	...	30 "
Soda carbonate	...	...	...	...	360 "
Potash bromide	...	...	...	...	$2\frac{1}{2}$ "
Water	...	...	...	...	10 oz.

This formula differs from all, which is the usual result of working to averages. If we change the sulphite to  $\frac{1}{2}$  oz. and the carbonate to 1 oz. in the 10 oz. formula, we get a result that approximates very closely to two of the published formulæ.

### A Museum of Ethnology.

The suggestion is made by a correspondent in the "Morning Post" of Monday last, that steps should be taken to establish a museum of ethnology in London, on a scale worthy of the opportunities for such an enterprise which are granted in the British Empire. There are already in existence several collections which would form the nucleus for the contents of such an "Imperial" museum, notably the Indian collection at South Kensington, which it is proposed to break up in the future. Photography for long past, and now of late colour photography, have been applied so exhaustively to ethnological research that the appearance and habits of almost every tribe may be shown in a manner second only to actual travel among the people. Such a museum would realise in a magnificent way the aims of those who, in the field of photographic record, have consistently kept to the front the importance of preserving records of the transient phases of life abroad as well as at home.

### Not for Competition.

There appears to be a growing custom among photographic societies of including in their annual shows many works labelled "Not for competition." It is easy, of course, to see how this comes about. A member gets tired of taking awards year after year, and is glad to retire from the contest, leaving an easier field for other competitors. But, it seems, the other competitors are at times inclined to resent this condescension. They wish still to try their steel against the retiring victor. That is sportsmanlike, no doubt; but is it the proper spirit to be fostered in a photographic society? It smacks rather of "pot-hunting," and reduces picture-making to a means, where it should be the end; justifiable emulation giving way to mere contest. To our minds the best way out of the difficulty would be for a rule to be made that when a member has taken, say, four awards his works should be no longer competitive. This would remove the personal element altogether; the retiring exhibitor being relieved from the unpleasant, haunting feeling that he is acting the superior person, whilst the rank and file would know when to expect that his works must be classed as *hors concours*.

### LARGE VERSUS SMALL SIZES—A BUSINESS QUESTION.

Of late years there seems to us to have been a tendency amongst middle-class photographers to cultivate business in the wrong direction, namely, by giving prominence to portraits of small size—postcards, midgets, and the like—at cutting prices, instead of working in the opposite direction—giving greater importance to pictures of larger dimensions, such as boudoirs, imperials, panels, etc., at a modest price. This is the more surprising, seeing that a single picture of these sizes carries as much or more profit to the photographer than do, perhaps, several dozens of the smallest sizes, of which such large numbers are now being done. Moreover, the larger sizes, if a good display of them were made, would decidedly improve the status of the business, while the prominence given the small sizes tends to lower it in the eyes of the general public. On mentioning this to a middle-class man, who is doing a fair business, the other day, he told us there was no demand for the larger sizes at the present time. It occurred to us that the "no demand" was to a great extent brought about by photographers themselves, by reason of there being no supply prominently shown; photographers as a rule do not make a feature of anything but small direct portraits, and of enlargements, mostly of

the common—we might almost say orthodox—20 by 16 size, which they can get done at a very cheap rate.

What seems desirable to us is to make a specialty of moderately large portraits, such as boudoirs, imperials, and panels. With regard to there being no demand for these pictures, it may be asked how many middle-class portraitists could at the present time show a decent number of specimens in these sizes if they were asked for them? Are the general public likely to inquire for things they may possibly know nothing whatever about? If a good display of them were made as is often done of post-cards and midgets by many photographers, there is little doubt that a demand would be created for this class of work, if only to a limited extent at first.

There is no question that large portraits, up to a certain size, taken direct, have a certain quality about them that is not possessed by enlargements of similar size. It goes without saying that to take portraits, say, of the panel size, about 12 by 7, and the large panel about 15 by 10, requires somewhat costly apparatus; that is, if portrait lenses are used for the purpose. But with the present extra rapid plates such lenses are not absolutely necessary. There are few professional photographers who do not possess a 12 by 10 or a 15 by 12 camera, furnished with a rapid rectilinear lens, for outdoor work. Either of these may well be utilised in the studio for large portraits. It is true that the lenses will be slower than portrait combinations, but in practice they are not so much so as many may imagine. A large portrait lens of wide aperture has to be stopped down to some extent in order to get the different planes of the subject in sufficiently sharp focus—sometimes even to  $f/8$ —in which case it is no more rapid than is a R.R. worked with its full aperture, and it will not have any greater depth of focus than will the latter, with its full opening. Hence it will be seen that there is no great obstacle in the way of any photographer doing moderately large direct portraits.

In taking the pictures, we would suggest that large heads be avoided, unless lenses of much longer focus be employed than are catalogued to cover the size plates just referred to. The reason for this is that large heads, when taken with the camera within a few feet of the sitter, are rarely satisfactory, by reason of the violence of the perspective—otherwise distortion—whatever form of lens be used. Full length or three-quarter length standing will as a rule prove the most satisfactory. For the boudoir size any whole-plate or cabinet lens of eleven or twelve inches focus will answer. Having got the negative, prints can, of course, be supplied at a moderately cheap rate, and yet carry a good profit.

It was mentioned just now that there is a certain quality in a direct portrait that is not possessed by an enlargement, but that may possibly require some little qualification, because by adopting a certain system there will be but little difference between the two; sometimes even there is a superiority in favour of the enlargement. But there is a way of making enlargements of moderate size that look very like direct pictures, and many years ago it was vended as a secret process for a substantial sum. The method is as follows:—Instead of making the enlargement on bromide paper, it is made as a transparency on a dry-plate the full size desired. From that transparency a negative is made by contact printing on another dry plate. From that prints can be taken by any process. The advantage of this system of working over that of first making a transparency the size of the original is that any defects pertaining to that would be magnified in the enlarging, although they were not in the original negative. A further advantage of this method is that the enlarged

transparency can be readily retouched, as the effect of the work will be seen exactly as it will be in the finished picture. For instance, the eyes or any part of the picture that may be a little out of focus in the original can be sharpened up, delicate shadows put in, and deep ones strengthened. In fact, any finishing that might be required on each individual print can be done, once for all, on the enlarged transparency. It may be argued that this way of working is more costly than the other, inasmuch as two large plates have to be employed instead of one. But this is not a matter of serious import when the best possible results are the principal consideration. If the transparency is made of a pleasing colour, and not too dense, it may, after it has served its purpose, be backed up with ground glass and used as a window decoration in the reception-room, in which event possibly it may be purchased by the sitter for a small sum, which will amply repay for the cost of using the plate.

The object of this article is really to suggest to middle-class photographers who are complaining of bad business at the present time that they might in the end find it more advantageous to cultivate a taste amongst their customers for portraits of a larger size than they are at present doing, but not necessarily of the commonplace, often badly made bromide enlargements so much in evidence. If the same prominence as is now given to a number of little pictures were given to those of moderate size, it would certainly tend to raise the status of the establishment, even if it did not for the moment bring more business to it.

#### UNION OF GERMAN PHOTOGRAPHIC PAPER MANUFACTURERS.

It is not generally known in England that some time ago the German manufacturers of photographic papers formed a Union, which has for its object the protection of their interests and the keeping up of prices. This step they considered necessary as a result of numerous discrepancies which had crept into the wholesale as well as into the retail trade. Photographers were able to buy their papers direct from the manufacturers at wholesale prices, and the general public could buy their papers at the large warehouses, which within the last few years have become a feature of shopping in Germany, at prices nearly as cheap as the dealer could himself procure these. The explanation given was that the warehouses, having a much larger turnover, could therefore buy in larger quantities than the dealer, and consequently were granted a larger discount. The result of this was that, in order to protect themselves, the dealers were obliged to boycott all manufacturers who supplied the warehouses, and who were thereby ruining their trade. It was in order to settle this difference that the Union of the paper manufacturers was arranged, and met so completely with the approval of the dealers that many of them have since become members of it. But the inner working of this Union is, so far, not quite as smooth as its members would like it to be. For one reason, some of the members of the Union had long contracts with the warehouse proprietors, and they have been obliged to fulfil their obligations, and this has led to some grumbling. The warehouses, on their side, are resenting this treatment, which obliges them to fall into line with the dealers and sell photographic papers at the same prices as the latter. Since it is the specialty of one and all of these warehouses to sell at low prices, they threaten to retaliate on the paper manufacturers, and either procure their photographic papers from other sources, or to manufacture them themselves. Since a very large section of the public using photographic papers are now in the habit of getting their papers from these warehouses,

it is questionable if the paper manufacturers can afford to neglect the warehouse custom. Consequently the situation is full of interesting developments, and it is to be hoped that some amicable compromise will be arranged before any serious crisis is brought about.

Meantime, the Union of Photographic Paper Manufacturers, which includes among its members most of the important paper manufacturers in Germany, has marked another stage in its history by holding its annual meeting.

## THE L.C.C. AND PHOTOGRAPHIC EDUCATION FOR GIRLS.

A BRIEF announcement was made in these columns some time since that a number of professional photographers had been invited by the London County Council to form an advisory committee in connection with a scheme for educating a certain number of girls, at the conclusion of their course of elementary education at the County Council Elementary Schools, in those branches of photographic work most fitted for female employment.

The general scheme for trade education of girls, which has now matured into established Trade Schools, may, perhaps, be described as a logical development of the Evening Technical Classes, which were established some years ago with a view to enabling working girls and women to improve themselves and gain greater skill at their respective trades. These technical classes still exist, and are doing useful work, but experience has shown that owing to the fatigue of long workroom hours, the necessity of performing domestic duties after work time, etc., comparatively few are able to avail themselves of them. As a means of supplying that technical training which is frequently incompatible with modern workroom conditions, the classes therefore leave ample room for other efforts in the same direction.

The greater proportion of girls on leaving the elementary schools must at once set about earning a living. They are, for the most part, suited by natural ability for handicraft trades, but pressure of poverty at home, or the mistaken desire to get good money at once often leads them to enter inferior unskilled occupations, and prevents them from giving the time expected to be given by an apprentice or learner. The result is that while there is an over-supply of unskilled or ill-trained and inefficient workers, there is a scarcity of intelligent hands who are thoroughly competent at their trades. Photographers will recognise that this is the case with regard to their own business, and that it is generally true is beyond doubt. The old-fashioned system of indentured apprenticeship which pledged the employer to teach his trade throughout to the apprentice and the apprentice to serve for a definite period has fallen generally into disuse. This doubtless is due partly to the reasons above stated, partly to the disinclination of young people nowadays to enter into any undertaking which may appear to affect their liberty, but probably more particularly to the tendency in modern manufacturing conditions to the specialisation of the workers. It is thus quite likely that any one entering a trade may never have the opportunity of learning more than one branch of it or even more than a simple operation. There seems to be no generally recognised method of training in any of the trades which were investigated in reference to the establishment of the trade schools for girls, and although in some trades indentured apprenticeship is still occasionally found, there appears generally to be a laxity in observing the provisions. In this connection it is satisfactory to learn that the L.C.C. has appointed an Apprenticeship Committee, whose duty it is not only to encourage and

Nothing of any particular importance to English readers was discussed at this meeting, except that it has been considerably strengthened by the addition of a considerable number of new members, who are mostly dealers. The photographic Press does not know exactly how to treat the Union, and the sum total of its criticism is confined more or less to a warning to the Union to be careful how it employs the powerful position in which it at present finds itself.

negotiate apprenticeships, but to keep in touch with apprentices and see that they and their employers are acting straightforwardly towards one another.

The Trade Schools are essentially of the nature of apprenticeship schools, and are intended to provide that thorough preliminary training without which there is little chance of the worker rising to the upper grades of her trade, and the system has the advantage over ordinary apprenticeship that the training may be wider, more thorough, and carried on under conditions better suited to young girls between the ages of fourteen and sixteen than is possible in the workroom.

The industries chosen for instruction so far are:—Corset-making, dressmaking, ladies' tailoring, costume designing and making (wholesale), upholstery, waistcoat making, millinery, and photography. These industries have been selected from among the many trades open to women in London after a careful investigation into the nature and condition of each. Only those trades have been selected which lend themselves to school training, and where there appears to be a demand and good prospects for intelligent workers. The general conduct of the schools is, of course, under the direction of officials of the L.C.C. Education Department, but the trade instruction is given by experienced teachers who have been practically engaged in the trades they teach, and is conducted on such lines as to familiarise the pupils with the routine of a business house. At the same time, to develop the general intelligence of the girls, lessons are given in general subjects—arithmetic, English, hygiene, drawing, and physical exercises. The schools are open from 9 a.m. to 5 p.m. About two-thirds of the time is given to trade work and one-third to general education. The course of instruction extends over two years, each pupil's course commencing at Easter, so that it may be completed at a suitable season for obtaining work. Consultative committees of trade experts are attached to each school. These experts visit the schools from time to time, inspect and criticise all the work done by the girls, and give advice on the technical requirements of the trades.

Pupils must be fourteen years of age or have passed Standard VII. Admission is obtained by means of:—

(1) Industrial scholarships, 126 of which were awarded in 1908, on the result of a competitive examination of girls from elementary schools whose parents do not earn more than £160 per annum. These scholarships entitle the holders to free instruction and to a maintenance grant of £8 the first year, and £12 the second year.

(2) Free places are awarded to some of those who have not succeeded in obtaining a scholarship.

(3) Paying pupils (at a fee of 10s. per term, £1 10s. a year) are received in all the classes.

About 375 girls are now under tuition. The first set of girls finished their two years' course at Easter this year. All these were readily found employment.

The school in photography was not started until Easter this

ear. The advisory committee, who accepted the invitation of the L.C.C. to act, consisted of Misses Muriel Bell, Cassels, and Caswall Smith, and Messrs. Ernest C. Elliott, Alexander Mackie, and Richard N. Speaight. On their recommendation Miss Brenda Johnson was appointed instructress. About fifteen girls are now under tuition, the number to be made up in time to twenty. The work at present includes mounting, spotting, and working up prints and enlargements, retouching negatives, printing and toning P.O.P. and other printing-out papers, and bromide and gaslight paper printing, but as the pupils get on at these further branches will be added. The pupils also constantly practise at drawing from the solid. It must be said that at the outset the committee were far from sanguine as to the success of the scheme. Their first visitation, made when the pupils had received three months' tuition, caused them, however, distinctly to change their opinions. On that occasion each pupil was personally examined both by questioning and by inspection of her work; and although, of course, the progress made was not uniform, even the most backward pupil gave promise of becoming a useful assistant after two years' training, while

the majority by keeping up their rate of progress would become quite expert at their work, and be certainly worthy of a much higher rate of remuneration than a girl of sixteen is usually able to command. The committee were particularly pleased with the thorough nature of the instruction the girls were receiving. They were all able to stand a searching examination as to every detail of procedure in their work, and to give the correct reason for it; often, indeed, to reply intelligently to questions the average operator or printer of rule of thumb methods, who nevertheless considers himself an expert, would stumble at. The efficiency of the school is distinctly creditable to Miss Johnson.

We await with interest further reports of the committee, and later on, when these girls are in employment, information as to whether they are able to adapt themselves readily to working under the usual conditions of a photographic establishment. If they stand the test well—and there is no reason why they should not—it may cause professional photographers to modify their opinions as to the inutility of technical schools for training assistants in practical work.

## HINTS ON PORTRAITURE.

[In the 1909 "American Annual of Photography," just published, we find a compilation of rules and counsels prepared with evident care by J. W. Little. There being many of the younger generation of photographers by whom such epitomised opinion is welcomed as an aid in their own study of portraiture, we have, in our last two issues, given the full text of the symposium, which is here concluded.—Eds. "B.J."]

The same attention should be given to the lighting of a face outdoors as indoors. This condition may usually be met by a suitable choice of location.

### Outdoor Work.

An outdoor portrait should convey the feeling that it was taken outdoors. The subjects should usually be in loose, comfortable costumes. Rustic seats may be used; but do not use chairs or other paraphernalia belonging to the house. The subject and the surroundings should not be incongruous.

The background in outdoor portraiture should be fairly well in focus, but it should be sufficiently diffused to produce a feeling of atmosphere behind the subject. If it is necessary to use a very undesirable background, it should be entirely out of focus, but not so much as to cause distraction.

Be sure that the background is not too elaborate, unless it is intended that it shall be a pictorial photograph, in which event the figures should be small and subordinated to the former. The sky, unless subdued, should not show close to the figures, and the background should not admit spots of light.

A too strong light, even indoors, contracts the pupils as well as the eyelids; therefore, when taking portraits outdoors and in strong light, be careful to see that the light does not strain the eyes of the subject. The eyes should rest on some dark object to avoid squinting, particularly if they be of light colour. If the sun is shining, it is better that it should be at the back of the subject and facing the camera, although it should, of course, not fall directly on the subject, and the head should not come directly against the sky.

A position near a large tree is often a good one in outdoor portraiture, the trunk of the tree shutting off the light from one side and the branches softening the light from above. The corner of two walls joining at right angles and in shade is often available as a good position, but an artificial background generally must be used. If the light is too strong from above, it should be softened by a piece of muslin suspended over the sitter.

The exposure outdoors will be governed by conditions, but it will usually be about three times that required for a landscape under similar conditions. If there are buildings near, shutting off much of the light, the exposure required may be greater.

A studio stand may be improvised by making a collapsible triangle of laths, fitting it with bed rollers, and using it as a base for a tripod by inserting the legs in holes on the upper side and at the corners of the triangle.

### Miscellany.

An anastigmat thrown out of focus does not give as agreeable definition as a cheaper lens (unless it is equipped with a diffusing device), because of the extreme contrast between the portions in and out of focus.

The lens should be racked out when it is desired to produce diffusion in portraiture. The focus should never be so soft as to destroy textures.

A lens of rather long focus is best, and it should be fitted with lens shade whether indoors or out.

The focus should usually be sharpest in the lightest parts of the portrait, which is most often the head; this may often be accomplished by a judicious use of the swing-back and a lens of large aperture.

Cap exposures may be made where there is necessity for silent shutter and it is not available.

Do not attempt to represent outdoor effects in the studio. If the figures are in outdoor costume, an imitation stone wall or fence may sometimes be necessary. In general, however, artificial gates, fences, balustrades, etc., should be avoided.

The environment of the sitter in the operating room should be light and cheerful. The furniture should not be obtrusive, and the upholstery should be plain, not patterned. The walls should be of light grey; the floor may be laid with matting or a simple carpet pattern, though these are often a disadvantage when moving the position of the camera and furniture.

Furniture of old and rustic patterns looks artistic in the reception room. The room should be well furnished and decorated. Some professionals prefer that the pictures hung in the studio should consist of engravings or platinum prints of the old masters, choosing for this purpose pictures which are not so well known as to be lacking in interest, and occasionally hanging with them some of the photographer's own best productions. Old armour, vases, etc., may also be used to decorate the studio, and

are likely to elicit interest on the part of patrons. The walls should be of some quiet colour.

The show window should be kept attractive, and the samples of work displayed should be changed often, so that the public will be constantly on the lookout for something new. Where high-class work is done, only a few selected pictures should be displayed; where the work is of a cheaper grade, the pictures displayed should be more numerous and of greater variety.

The inside covering of packages of photographs for postage look better sealed with a label of artistic design than tied with twine.

A proof should seldom be sent to a customer from a who, unretouched negative, as it is likely to make a bad impression. It is better to have the name of the studio on the back mounts, but, if on the face, it should be small, of artistic lettering, and of a colour to harmonise with the print.

It is usually better to yield to a client's wishes, and make negative in the position or with the accessories desired by him, and then make another in accordance with your own judgment. It is more likely that he will choose the latter when the proofs are sent him, or he may even increase his order by ordering prints from both.

J. W. LITTLE.

## AN EXPERIMENTAL STUDY OF THE LIPPMANN COLOUR PHOTOGRAPH.

PHOTOGRAPHY in colours by means of standing light-waves was first done by E. Becquerel about 1850, although he was unaware of the part they played in his results. Zenker<sup>1</sup> developed the theory that the polished silver surface, on which Becquerel's sensitive film was formed, reflecting the incident light, caused standing waves. In the loops of these waves the silver salt was reduced, forming parallel reflecting surfaces distant from each other one half the wave-length of the incident light. Viewed by reflection the developed film exhibited colour as do thin films of oil on water, or, more exactly, the multiple interior surfaces of potassium chlorate crystals.<sup>2</sup>

Lippmann<sup>3</sup> in 1891 was the first to make practical application of this theory by developing the process of colour-photography bearing his name. For the polished silver surface of Becquerel he substituted mercury, which could be flowed behind a transparent fine-grain sensitive film on glass during the exposure, and removed to permit development and the subsequent viewing.

The theory and practice of the process will be found discussed by Lippmann,<sup>4</sup> Wiener,<sup>5</sup> Neuhauss,<sup>6</sup> Valenta,<sup>7</sup> Lehmann,<sup>8</sup> and others.<sup>9</sup> Full use has been made in the following study of the results of their work, and details of theory and experimental methods not new with the writer will not be described at any length.

Good results have been obtained by the process as worked by these and other experimenters, but its difficulties have been found so great as to prevent its wide use. Some discrepancies with the theory have been found, and compromises with the best conditions as indicated by theory have been found necessary in practice.

The object of the present investigation has been to see how closely the conditions called for by theory could be approached, to find the cause of some of the difficulties met with in practice, and, if possible, to obviate these.

The separate problems will be stated as they are taken up, but may be briefly outlined here.

According to the theory, as stated by Lippmann, the most accurate reproduction of colour should come from the use of a thick sensitive film, the film gaining in resolving power with the number of reflecting laminae. In practice very thin films have been used; reproductions of the spectrum show, on examination with the spectroscope, that the colours are very far from pure. The first investigation which follows was to determine whether films could not be prepared which would reproduce colours with a fidelity much greater than has hitherto been possible, and whose thickness could be increased with corresponding increase in resolving power. The investigation has resulted in a method for producing films having these characteristics.

The production of pictures of natural objects has been a matter of uncertainty and difficulty; the production of whites has been a stumbling-block to many. The manipulation of the plates with the necessity for a mercury-holding plate-holder has been inconvenient. The causes of this uncertainty in results have been studied; the conditions governing the production of white fixed; and a substitute found for the hitherto indispensable mercury mirror.

In addition, an application of the process to three-colour photography has been developed.

### Manipulation of Plates in General.

The transparent fine-grain silver bromide plates were made, with only such changes as are noted, according to the published formulae of Lippmann, Neuhauss and Valenta. Ordinary "chemically pure" silver nitrate and potassium bromide were used; the gelatine was either Eimer and Amend's "Gold Label," Nelson's "No. 1," or a department store gelatine recommended as the best for puddings, etc., which was found very hard and free from grease. The emulsion was flowed on pieces of crystal plate glass cut three by three inches. A plate-holder not greatly different from that used by previous workers permitted the introduction of mercury behind the plate and in contact with the gelatine.

The scheme of exposure followed throughout was to expose a comparatively large surface (two by two inches) to the kind of light being investigated. This allowed of easy spectroscopic examination besides leaving room for stripping portions to be sectioned.

Development was mostly with pyrogallol acid and ammonia according to the formula of Valenta, with the one change that the pyrogallol acid was used in powder form, added by means of a spoon of proper capacity to the rest of the developer just before use with each plate. The resulting developer was always fresh and of uniform strength. The hydroquinone used in part of the work was made up according to Jewell's formula<sup>10</sup> with the omission of the potassium ferrocyanide.

After development and drying, the pictures were made ready for viewing by cementing a thin prism of small angle on the film to destroy the disturbing surface reflections, and the back of the glass flowed with asphaltum varnish. The prism is usually cemented on by means of Canada balsam. As, however, the refractive index of the gelatine containing reduced silver is somewhat higher than that of the balsam, some medium of higher index is to be preferred. Gum styra<sup>x</sup> ( $\mu = 1.58$ ) was found suitable, but the lower surface of the prism must be ground to avoid the reflection at glass-balsam surface. The latter procedure was uniformly adopted. The amount of light reflected from the laminae is at best small, so to obtain the purest colours all addition of white light is to be avoided. This white light may come from the prism-balsam, balsam-gelatine, gelatine-glass, or rear glass surfaces, and if all these reflections are not diminished as much as possible the dilution of colours is quite appreciable. The prism-balsam reflection is overcome by grinding the back of the prism with emery, the balsam-gelatine by correct choice of balsam, the gelatine-glass is unavoidable, the reflection from the back of the glass can be completely destroyed

by first grinding with emery and then flowing on asphaltum varnish, preferably mixed with machine oil, to prevent its becoming brittle and flaking off. If the pictures are to be observed from the glass side a second prism is cemented on in place of the black varnish.

When so mounted the pictures are ready for observation. It is of extreme importance that they be observed by parallel light and shielded from all side light. The best conditions are given by a small opening in a wall facing a brilliant white sky. If the observer stands with his back to the opening and holds the picture at arm's length reflecting the sky it appears at its best.

These precautions are most necessary in the case of pictures of natural objects, for reasons which will appear later. Spectra and similar subjects, where the reflecting laminae are numerous and deep in the film, are visible much more easily, but are, of course, best seen under the conditions given above.

### Work with Monochromatic Light Sources.

The first investigation was on the influence of two factors, fineness of grain and film thickness, upon the correctness of colour rendering. It is naturally to be expected that both factors will influence this. The smaller the silver particles the more minute the variations in the standing wave system they will record. The thicker the film the more laminae, and hence the greater purity of the reflected light.

There are comparatively few recorded experiments on variations in the size of the grain; the first published emulsion formulæ have been closely followed by all experimenters. Cajal<sup>11</sup> recently observed that the size of the grain is influenced largely by the amount of agitation of the emulsion during preparation, and finds that the finer the grain, the better the quality of the colours. He, however, was not working with pure spectrum colours. The present investigation of this point was prompted by the observation that when photographing monochromatic light sources for a special application of the process the use of much less silver bromide gave more satisfactory results. This made it appear of interest to determine from this standpoint the best proportion of silver salt.

With regard to the best thickness of film, theory would call for the greatest thickness practicable to work. Yet the practice has been to work with extremely thin ones such as can be obtained by flowing the liquid gelatine on and off a warm glass plate. The section photographed by Neuhauss showed but seven or eight laminae. Wiener, by counting the laminae cutting the gelatine-glass surface in a spectrum photograph, found the number less than twenty, obviously too few to have much resolving power, and explaining the impure reflected light. There has, indeed, been reason to suppose that appreciably greater thickness would not help matters. The loss of light by absorption and reflection at each lamina is large, so that the effect of each lamina becomes rapidly less with increasing distance from the surface of the film, assuming them all equally well formed. Film sections indicate the latter is not the case, the laminae are of rapidly decreasing strength. Lehmann has calculated, taking into account the effect of absorption, that the laminae should be more distinct the greater the distance from the mirror. That they are not he ascribes to the reflected light losing the power of interfering after a short distance. These points were considered worth investigating more closely.

The size of the silver grain was varied entirely by the quantity of silver bromide in the emulsion. A set of emulsions was made up in which the content of silver nitrate varied between .03 and .18 gram per gram of gelatine, the quantity of potassium bromide constantly five-sixths of this. The resulting emulsion had from one-sixth to the same amount of silver bromide as used by Valenta and others. The emulsion was flowed on the level plates in measured quantities from a graduate, so that the thickness was under control. After flowing, the emulsion was pushed to the corners of the plate by means of a glass rod. The quantity used varied from one to ten cubic centimetres on a 3 in. by 3 in. plate. This gave films from about .077 to .07 mm., as section afterwards showed by the number of contained laminae.

Monochromatic green light was used for the greater part of the work. This was obtained from a Cooper-Hewitt mercury vacuum lamp, an aperture of 1 sq. cm. illuminating the plate 25 cms.

distant. A cell of neodymium ammonium nitrate and potassium bichromate absorbed the yellow and blue radiations. The plates were made sensitive to this colour by erythrosine.

### Influence of Size of Grain.

A noticeable increase of purity in reflected light was found as the quantity of silver bromide was reduced. This increase is quite marked between .18 and .09 grams of silver nitrate per gram of gelatine; after that less so.

Besides the influence on the purity of the reproduced colour the quantity of silver bromide affects the sensitiveness of the plates. A rather unlooked-for result was that a smaller quantity of silver salt made the plates more sensitive, up to a certain point. This is readily explained. The light must pass through the film, and decreasing the silver content increases the transparency. If the amount of silver becomes too small the plates again become less sensitive. The fastest emulsion was found to be one containing half the silver salt used by previous workers. As this gave practically all the increase of purity resulting from decreased grain it was adopted as the standard emulsion for future work.

The formulæ and method of preparation were as follows:—

A. Gelatine, 1 gram. Water, 25 cc.	B Gelatine, 2 grams. Potass. bromide, .25 gram. Water, 50 cc.	C. Silver nitrate, .3 gram. Water, 5 cc.
---------------------------------------	---	---

A and B are heated till the gelatine melts, allowed to cool to 40 degrees, C added to A and then A to B slowly with stirring, the sensitiser added, and the whole filtered. After flowing and setting, the plates are washed for fifteen minutes and allowed to dry.

### Influence of Thickness of Film.

The first work done on the influence of film thickness indicated that, viewed from the film side, there was no increase of purity with increase of thickness beyond one of about thirty half wavelengths, or about that given by flowing the emulsion on and off the cold glass plates. The single green line of mercury was rendered as an ill-defined green band in the spectrum, properly a continuous spectrum with strong maximum in the green. The green light is considerably more monochromatic than usually seen in Lippmann spectra. From the glass side the band was of a different character, showing more clearly defined edges. This is explained by the stronger laminae being farther from the eye and by absorption being no more effective than the weaker ones. The reflecting surfaces are then comparable to the lines of a grating, each sending equal contributions to the total reflected light. Owing to the strongest laminae suffering so much absorption the light from the glass side is much weaker than from the film side.

Even from the glass side, however, increase of thickness beyond the above given limit produced no corresponding increase of purity. Further light on this question was furnished by studying the effect of varying exposure and development.

### Effect of Varying Exposure.

To study this, exposures were made through a graduated wedge of erythrosin solution, opaque to green light. Before noting the effect of varying exposure on the reflected coloured light, the appearance of the film at angles other than the angle of specular reflection is worth describing. By reflected light the film appears in the less exposed parts like an ordinary fine-grain negative—that is, there is a certain amount of diffuse reflection, so that a positive image is seen. As the exposure proceeds the diffuse reflection becomes less and less until the film is quite grainless and black, except at the angle of specular reflection, behaving as a piece of unsilvered glass. By transmission the plate is greenish in the very slightly exposed parts, muddy brownish yellow in the moderately exposed parts; where the film has been exposed until the diffuse light disappears by reflection it is clear transparent yellow, like a piece of yellow glass. The appearance and behaviour of the silver deposit is in all respects as though the particles of silver were first separate, scattering light, and on longer exposure fused together into a homogeneous mass. The appearances here described may be observed on almost any Lippmann photograph viewed at other than the angle to show colour, the diffuse deposit forming a positive image which in the fully exposed high-lights appears reversed.

The coloured light reflected from the laminae increases in intensity with increase of exposure until the diffusely reflected light disappears; after that for a long range of exposure no change in

<sup>11</sup> "Zeitschrift für Wiss. Phot.," July, 1907. Page 213-245.

intensity occurs. This is probably because the individual laminae do not gain in reflecting power after the silver particles have fused together into a reflected surface. This fact makes it possible in photographing spectra with plates not evenly sensitised to secure uniform action throughout the spectrum merely by long exposures.

The greatest spectral purity of the reflected light occurs just before the "saturation" point is reached, dropping slightly for longer exposures, and not changing perceptibly till many times

Fig. 14.

the full exposure, when the colour tends toward grey and white. From the glass side the purity increases with exposure to a maximum, and then remains constant except with very thin films, in which case the purity again decreases. The cause of this will appear shortly.

#### Effect of Varying Length of Development.

By lowering a plate slowly into the developer different amounts of development were obtained. The only effect of greatly increased development was to cause fog, decreasing somewhat the purity, if the picture was viewed from the film side. Viewed from the glass side longer development had no effect whatever, except with thin films, when the purity decreased similarly to the effect noted with increasing exposure.

The practice was to develop the plates up to the point where fog

Fig. 5.

begin to appear, usually by time development. At temperatures near 20 deg. C from 45 seconds to a minute gave full development.

#### Action of the Developer on the Film.

Using thick films it was found, if development was sufficiently prolonged, the laminae intersected the gelatine-glass surface, giving a watered silk effect, the same phenomenon used by Wiener to estimate the thickness of the film. As in film sections heretofore made, comparatively few laminae had been found, it has been assumed that but few are formed. The appearance just noted indicated that the laminae might be formed throughout the thickness of the film, provided development were continued long enough.

To study the action of the developer it was decided to section the films and observe them under the microscope. This has been done by Neuhauss, Lehmann, and Cajal. The latter swells the section in water to bring the structure, in its natural size too small to be satisfactorily resolved with the microscope, within reach of average powers. This method was pursued in the present investigation. After development a small oblong of film was cut out with a knife and then stripped from the glass by means of a narrow straight-edged chisel. The strip of film was then laid on one half of a split piece of pith. When dry, the other half of the pith was laid over it, the whole placed in a microtome and sectioned. On laying the sections on a microscope slip, and wetting with a drop of water, the majority of the laminary structures were easily observable with a one-sixth inch objective. For much of the work where it was not important to have sections of exactly the same thickness it was found convenient to dispense with the microtome, simply holding the pith in a pair of clothes pins and shaving off sections with a razor guided by the fore-finger, an operation easily performed after a little practice.

A section of a normally exposed and developed film is shown in Fig. 5. It will be observed that the laminae are strongest at the mirror-surface, decreasing in strength with distance from it.

Fig. 6.

Fig. 7.

Figs. 6 and 7 (sections of same thickness) show the result of short and long development. With short development the laminae are visible for only a short distance; with long development the laminae are present to a great depth, but a thick band of fog has progressed inward from the surface. The laminae corresponding to the surface ones in the short development are therefore in the long development at a greater depth. From the glass side their effect is precisely similar, unless the film is thin or development has been very long, in which case the fog band reaches to the glass and drowns out the clearly formed laminae. This makes clear the above noted effects of long exposure and long development as seen from the glass side. A film exposed or developed progressively from edge to edge possesses a layer of well-formed clean laminae running diagonally down from the surface until the glass is reached.

HERBERT E. IVES.

(To be continued.)

CINEMATOGRAPH ACCIDENTS.—The West Ham Town Council some time ago wrote to Whitehall, pointing out the need for regulations in respect to cinematograph entertainments, which at present are free from restrictions, and which are a source of risk to persons attending the same. They have now received a letter from the Home Office, stating that the question from the point of view of public safety is receiving the attention of the Home Secretary.

## ILFORD, LTD.

## INCREASED SALES DESPITE KEEN COMPETITION.

The ordinary general meeting of Ilford, Ltd., was held on December 1, at Winchester House, E.C., Colonel Ivor Philipps, P., presiding.

The Secretary (Mr. Fred. J. Jenks) having read the notice and the report of the auditors,

The Chairman, in moving the adoption of the report and accounts for the year ended 31st March 1908, said: Dealing with the declaration of the dividend recommended, said: Dealing with the balance-sheet, you will see that the goodwill stands at a large figure of £222,000, and last year we wrote nothing off that amount. Under freehold land, buildings, etc., we brought forward an amount of £78,114, and we have added since £5,952, on account of additional land we have purchased at Ilford and also on account of new buildings which we have found it necessary to erect at Ilford to carry on your business properly. The depreciation is written off exactly on the same basis as in previous years, and you will see figures at £2,600, as against £2,700 last year. The net increase under this heading of freehold land, buildings, etc., is £1,300, of which very nearly half is the value of the additional freehold land. The investments are entered at cost, as in previous years, and are exactly the same as before. They have fortunately appreciated by about £700 during the year, but the market value is still about £5,800 less than the book value. This year we have set aside £1,000 to reduce this disparity. The sundry debtors show an increase, owing to the increased sales and the general development of our business. Stock figures at about the same, but is really in a much more favourable condition, because this year the manufactured stock is less and the unmanufactured stock is more, consisting largely of nitrate of silver, which we were fortunate enough to buy at a very favourable price, so that a large quantity of your stock is available supposing we should be in such an unfortunate position as that we wanted to realise it, which we are not. The cash at bankers shows an increase of about £14,000. Turning to the profit and loss account, the salaries, advertising, rates, taxes, and sundry trade expenses are about £15,000, against £18,000. This is owing to our having no managing director at present, and also to a certain saving the secretary's and other salaries. Directors' and auditors' fees are also somewhat less, owing to the death of our colleague, Mr. R. Smith. Turning to the credit side, the profit on trading account is £46,000, against £34,000, an increase of close upon £12,000, or about 35 per cent., which I am sure you will agree with me is comparatively satisfactory. The balance carried to the balance-sheet is £28,810, against £14,000 last year, or more than double. (Applause.)

Sales show a very satisfactory increase, although competition does not show signs whatever of slackening. When you consider the disastrous state of trade generally in the country, and remember that our manufactures are used in great part for what may be termed luxuries, I think you may view the outlook with considerable satisfaction, for in this bad year for trade you have not only kept level, but have gone ahead. It was only reasonable in a period of such bad trade to expect a decrease in your output. I referred last year to the price-cutting that was going on, and said we hoped and expected there would soon be more reasonable conditions, but those hopes and expectations have not been fulfilled, and in this direction matters are rather worse than they were before. The Board are very much indebted to a number of shareholders who sent us privately criticisms upon the way we bring our goods to the notice of the public, and to various other suggestions. I should like to point out that we have to meet very severe competition indeed, and to my mind the very best way in which shareholders can benefit the company and improve their property is by bringing their suggestions or criticisms privately to the notice of the Board. We always consider them, and we adopt them where we think any benefit will accrue. The new productions of your company are very highly appreciated, and I do not think I am going too far in saying that the high standard for which your company has always been well known has not only been maintained, but the quality of your goods has been greatly improved in many directions. Mr. Knobel resigned his seat on the Board after the last general meeting, as was arranged, and, according to the promise which I then gave on behalf of the Board, the vacancy thus caused has not been filled up. One of our colleagues, Mr. A. R. Smith, has died since I last came before you, and I regard his death

as a distinct loss to the company. To fill the vacancy thus caused, the Board have elected Major Evatt. This gentleman was known to me as having great powers of organisation. He is an enthusiastic photographer, is energetic, and has time at his disposal. He is also a large shareholder. In Major Evatt you have a most excellent director, who is immensely interested in everything to do with your work, and I think he will be a very valuable asset to the company. We have, as you know, no managing director at present. Mr. Zerffi, who was your commercial manager, we have appointed general manager; and Mr. Jenks, who is an old servant of the company, is now your secretary. I wish before sitting down to express my appreciation of the work done by your staff generally.

## THE SAFETY OF THE PUBLIC.—PREVENTION OF FIRES.

The following is the text of a report presented by the Kinematograph Manufacturers' Association of Great Britain in reference to the prevention of fires in cinematograph exhibitions:—

One of the earliest subjects considered by the Kinematograph Manufacturers' Association of Great Britain was the question of the safety of the public at exhibitions of animated pictures, which was considered of vital importance. It was felt that one of the most effective means was to ensure that the operator had a thorough knowledge of his work. For this reason a scheme was set on foot for the examination and certification of operators and exhibitors, and the association was fortunate in securing the co-operation of the Northampton Polytechnic Institute, of London. These examinations, of which two have already taken place, are held under the aegis of a Joint Committee of the association and the institute.

The association has also carefully considered various means of improving the apparatus with a view to minimising the risk of fire. When the London County Council last autumn proposed certain legislation in respect to cinematograph exhibitions, the secretary of the association wrote the Clerk of the Council as follows:—

November 18th.

## RE KINEMATOGRAPH EXHIBITIONS.

"Having regard to the proposed legislation on the above, I am requested to ask if your committee would be disposed to receive a deputation from this association to explain their views on the needs of the industry, and the scheme (detailed in the enclosed pamphlet) for certifying the proficiency of operators and their acquaintance with your regulations."

On December 2nd the Clerk of the Council replied to the secretary of the association as follows:—

"I submitted to the Theatres and Music Halls Committee of the Council your letter of the 18th ult. asking, in view of the possibility of the introduction of legislation with regard to cinematograph displays, that a deputation from the K.M.A. of G.B. may appear before the committee with regard to the needs of the industry, and I am directed to inform you that the committee will be prepared to receive the proposed deputation at 4 p.m. on Wednesday, the 11th inst., at this office.

"In accordance with the practice obtaining in such cases the deputation should not consist of more than ten members, and only one will be at liberty to address the committee.

"I have also to request that you will forward to me as soon as possible before the 11th inst., a full statement of the points which the association claim to place before the committee."

Accordingly, the deputation, consisting of seven members of the association, with Mr. R. W. Paul, the then chairman of the association, as spokesman, attended the meeting of the Theatres and Music Halls Committee at the offices of the London County Council, Spring Gardens. The following suggestions as to safety precautions were put forward:—

## SUGGESTIONS AS TO SAFETY PRECAUTIONS.

1.—That every operator, before being allowed to exhibit in a hall or shop under the control of the Council, should be required to possess a copy of the regulations for cinematograph exhibitions, with a statement signed by the operator to the effect that he has read and understood the regulations.

2.—That the lessee of every hall and shop regularly or periodically used for cinematograph exhibitions should provide a metal-lined compartment or a fire-proof room of construction approved by the Council's engineers, and shall be responsible for seeing that the

projecting apparatus is installed in such a compartment or room when in use.

3.—That no resistance shall be approved for use with a kinematograph projector if its temperature rises more than 80 C.\* above that of the surrounding atmosphere, and no such resistance shall be fixed inside a fire-proof compartment at a lower level than the base of the lantern.

4.—That no fuse shall be allowed inside a fire-proof compartment unless of the double-pole pattern and enclosed in a separate fire-proof box.

Furthermore, the committee respectfully suggest the following revision to the regulations at present in force:—

Clause 4.—That the body of the lantern shall be constructed of metal and not of wood or other non-conducting material.

Clause 9.—That under this clause the Council shall, after December, 1908, be empowered to require the operator to produce a certificate of competency, obtained by passing one of the examinations held under the management of the Joint Committee of the Kinematograph Manufacturers' Association and of the Northampton Polytechnic Institute, these examinations being independent of any trade influence and including a practical test of the proficiency of the candidate in working a kinematograph exhibition.

Details of the scheme, including syllabus of the examinations and regulations for registration of competent operators, were set forth in a booklet submitted.

The first examination under this scheme was held in October, 1907, and a satisfactory number of candidates attended, those who succeeded in passing the examination having been placed on the register of certified operators, a copy of which was presented to the committee.

Nothing further was heard officially from the London County Council until July 31st of the present year, but on making inquiries the association was given to understand that the Council had dropped the idea of introducing a Private Bill in Parliament in respect to this matter in favour of a short Bill, which it was thought would be introduced by Mr. Gladstone, the Home Secretary, and this decision was verified in a later letter from the L.C.C.

On the above date the Clerk of the Council wrote the secretary of the association as follows:—

31st July, 1908.

"The attention of the Theatres and Music Halls Committee of the Council has been drawn to an apparatus for immediately extinguishing fire in the event of the film in a cinematograph lantern becoming ignited. The apparatus is very simple in construction, and practically consists of a sprinkler, which is automatically set in action by the heat generated by the burning film. The committee have inspected the apparatus, and in view of its simplicity and effectiveness, they propose to recommend the Council to add to its regulations respecting the use of cinematograph lanterns in premises licensed by the Council a regulation requiring the use of some apparatus for immediately and automatically extinguishing the fire in the event of the film becoming ignited.

"Before submitting any recommendation to the Council, the committee will be glad to consider any observations which the Kinematograph Manufacturers' Association may wish to make upon the proposal, and I have to ask that you will be good enough to let me have any such observations by 1st October next.

"With regard to the amendments which the deputation from the association, which attended before the committee on 11th December, 1907, suggested should be made in the Council's cinematograph regulations, I have to state that the committee adjourned consideration of the suggestions pending the introduction of legislation dealing with cinematograph exhibitions. As, however, the Home Secretary has not, as was hoped by the Council, introduced a Bill upon the subject, the committee propose to consider the suggestions at their next meeting, and I will communicate to you any decision which may be arrived at."

This letter was discussed by the executive of the association, and the secretary was asked to write to the Clerk of the London County Council asking for further particulars of the extinguisher referred to,

\*This was a clerical error and a letter was forwarded to the L.C.C. pointing out the mistake, and stating that it would no doubt have been noticed by the Council's engineer.

and suggesting that it would be desirable for the members to have the apparatus demonstrated to them previously to the meeting on October 1st. This letter was sent under date September 4th, and was as follows:—

"In further reply to yours of July 31st, I am instructed by my committee to inform you that the K.M.A. are keenly alive to the importance of any safeguard against the danger to the public due to the inflammability of celluloid films. My committee feels, however, that it cannot endorse the recommendation of any device which has not been tested by the association, and I am instructed to request that you will give the committee an opportunity of investigating and testing the automatic sprinkler to which you allude.

"I am further directed to inform you that the committee will be glad to make all necessary arrangements for carrying out the test either on your premises, or elsewhere by arrangement."

In reply to the above, the Clerk of the Council wrote under date September 28th, as follows:—

"With reference to your letter of the 4th inst. with regard to the proposed amendment of the Council's cinematograph regulations, I understand that Mr. Thomas Barrasford, 11, Leicester Place, proposes to arrange for a demonstration to be given with an apparatus for extinguishing fires in cinematograph lanterns, and I have, therefore, to suggest that you should communicate with Mr. Barrasford with a view to representatives of the K.M.A. of G.B. attending the demonstration.

"The Theatres and Music Halls Committee of the Council will again consider the matter on the 14th October, and I shall be obliged if you will let me have a definite reply to my letter of 31st July before that date."

It appears from the above that the L.C.C. postponed their date for the demonstration until the 14th October, and it was reported that the apparatus in question. On September 26th the secretary of the association wrote to Mr. Barrasford as follows:—

"I am informed by the Clerk of the L.C.C. that you propose to arrange for a demonstration to be given with an apparatus for extinguishing fire in cinematograph lanterns. I should be pleased to hear when it will be convenient for a deputation of this association to see the apparatus, so as to enable a report to be made upon its working to the Theatres and Music Halls Committee of the Council, if requested."

No reply was received. Consequently, the secretary wrote again to Mr. Barrasford on October 3rd as follows:—

"With further reference to my communication of the 26th ult., and as we are asked by the L.C.C. to submit a report on your apparatus by October 14th, would it be convenient for my committee to see you working on Thursday next, October 8th, at 3.0 p.m.?"

No reply being received to this letter either, the secretary wrote the Clerk of the Council on October 8th, laying the facts before him as well as copies of the letters which had been sent to Mr. Barrasford. On October 15th the following letter sent by Mr. Barrasford by messenger to the Holborn Restaurant was handed to the secretary of the association. It was written on October 14th, which was the very day the L.C.C. had offered to receive a report upon the working of the apparatus:—

"Kindly call and see the kinematograph fire extinguisher any time to-day before the meeting."

The matter, therefore, dropped for the time being, but was revived by Mr. W. Reynolds, a member of the L.C.C., who pioneered the demonstration of the above-mentioned apparatus at the Hippodrome on November 26th. Notice of this demonstration was sent to some members of the trade, but many prominent members were omitted, notably some who were represented on the deputation to the London County Council. However, several members of the association were present at the demonstration, and it was proved that the extinguishing properties of the apparatus were good, but it was liable to be accidentally released. The inventor himself accidentally deluged his films and apparatus with water while preparing for the demonstration. Mr. W. Reynolds threatened the members of the trade with the passing of legislation at Christmas, enforcing the use of a device similar to the one he had exhibited, in all halls under the jurisdiction of the L.C.C. Various gentlemen present mentioned that there were on the market various apparatus for automatically extinguishing fire without the liability of accidental destruction inseparable from the apparatus exhibited by Mr. Reynolds, and at the instance of some members of the Kinematograph Manufacturers' Association

it was arranged to have a demonstration of these devices. Mr. Stoll volunteered to place the Hippodrome ring at the disposal of the trade for the purpose, at a date to be fixed later, and both Mr. Reynolds and Mr. Barrasford said they would give their hearty support to any contrivance which proved its efficiency. It was further stipulated by the members of the association that the competitive demonstration should be given under working conditions such as obtain in public exhibitions.

## Exhibitions.

### THE NORTH MIDDLESEX PHOTOGRAPHIC SOCIETY.

THE twentieth annual exhibition of this society was opened on Dec. 3 at Hanley Hall, Sparsholt Road, N. Unusual enterprises had been exercised by a few of the members, who had between them designed and carried out an enormous banner which hung across the end of Sparsholt Road, and must certainly have proved useful in attracting strangers. The catalogue this year is also a dignified-looking quarto, well produced, and boasting of a good interpagination of advertisements. On the whole the pictures, excellent as they were, did not strike us as passing in interest those of recent years; but, considering the high standard of those, such a thing is not surprising. The president, Mr. H. W. Fincham, exhibited thirteen pictures, besides prints, in the record section, and transparencies. His view in Ely Cathedral of "A Norman Arch" (50) has much dignity and style, and is perhaps the best of his works. Mr. Stewart remains true to the oil process, contributing five out of the total eleven in this method. The finest is "January" (19), a noble landscape, excellent in every way. Some of the others do not surpass the standard of his former successes. "A Lady of Quality" (1) is an eighteenth century costume piece of much charm, by C. A. Morgan. A. H. Piddington's "Corn Ricks" (15) and S. E. Wall's "Winter Showers" (20) are two extremely choice works, and A. H. Lisett's spirited "Folly" (46), the face of a laughing woman, should attract much attention. "Waterside—Chesham" (60), by J. C. S. Mummery, is a work of much quality and an object-lesson to others who so far have not passed into the higher stages of pictorial art. Space prevents more than mere mention of excellent works by Messrs. Beadle, Puddy, Mattocks, Turner, Black, and Harbert.

As usual, there was a large collection of good lantern slides, as well as thirty-nine Autochromes, which were well displayed by the optical lantern. The judges were Messrs. A. H. Blake and B. Gay Wilkinson, whose awards were as follows:—

(1), "A Lady of Quality," C. A. Morgan; (40), "The Evening Ebb," M. F. Black; (52), "Early Morning—Ely," H. W. Fincham; (54), "The Harbour," E. C. Ridge; (65), "Morning," A. H. Lisett; (77), "Smoke and Grime on a Flowing Tide," D. P. Fox; (88), "In the Woods," C. Beadle; (120), "The Edge of the Spinney," A. H. Piddington; (140), "An Al-Fresco Luncheon," W. Pringle.

Lantern Transparencies.—(266), "The Fountain," W. Pringle. Colour Transparencies.—(373), "Old Chingford Church," F. J. Nisbett.

Hon. Mention.—(11), "Dittisham Beach," W. Jackson; (23), "The Chapel Gates," H. W. Fincham; (26), "Sunset," C. A. Morgan; (55), "The Arrest," W. Pringle; (78), "A Mediæval Gateway," D. P. Fox; (135), "The Edge of the Forest," E. R. Mattocks. Lantern Transparencies.—(257), "A Sunshine Effect," E. Burton; (279), "Monte Cristillo," C. H. E. West; (315), "The Decorator," E. Barnard.

Colour Transparencies.—(370), "Gladioli" and (371) "Old China," F. J. Nisbett.

On Thursday evening, the 3rd inst., Mr. H. W. Fincham delivered a lecture upon "Ely Cathedral, the Queen of the Marshlands"; on Friday, the 4th inst. Mr. J. McIntosh lectured upon "The Thames," showing his Autochrome plates; and Mr. W. L. F. Wastell's popular "Afar in the Fatherland" delighted the Saturday audience.

AN APPRECIATION of the pioneer work and writings of the late F. H. Wenham in the field of aerial navigation is contained in the current issue of "Aeronautics" in the shape of a review of Mr. Wenham's papers of forty years ago by J. H. Ledebor. "Aeronautics," we may add, is the supplement to our contemporary, "Knowledge and Illustrated Scientific News," in which progress in aerial flight is recorded.

### FORTHCOMING EXHIBITIONS.

December 9 to 12.—Bolton Amateur Photographic Society. Secs., A. N. H. Wylde and J. Bailey, 25, Croston Street, Bolton.

December 30 to January 2.—Chelmsford Photographic Society. Entries close December 17. Sec., M. J. Morison, Savernake Lodge, Chelmsford.

December, 1908, to January, 1909.—Kiew International Photographic. Sec., S. I. Horovitz, Technical Society, Kreshchatik, 10, Kiew, Russia.

1909.

January 1 to 9.—Scottish National Photographic Salon. Sec., Robert Telfer, 138, Glasgow Road, Wishaw.

January 6 to 27.—Northern Photographic (Manchester). Entries close December 11, 1908. Sec., S. L. Coulthurst, Broad Oak Road, Worsley, Manchester.

January 19 to 30.—Glasgow Southern Photographic Association. Entries close December 30, 1908. Sec., Robert Lindsay, 189, Allison Street, Glasgow, S.S.

February 10 and 11.—Cowes Camera Club. Sec., E. E. Vincent, 4, High Street, Cowes.

February 20 to March 20.—South London Photographic Society. Sec., H. Creighton Beckett, 44, Edith Road, Peckham, S.E.

February 22 to March 6.—Birmingham Photographic Society. Entries close for abroad January 5, for England, February 12. Sec., Lewis Lloyd, Church Road, Moseley, Birmingham.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for patents have been received between November 23 and 28:—

PHOTOGRAPHIC PICTURES.—No. 25,126. Method of producing photographic pictures or designs having special properties. Alfred Brewerton Craven, 20, Edinburgh Road, Armley, Leeds.

DEVELOPMENT.—No. 25,370. Improved method of and means for determining the process of development of sensitised plates. Arthur Augustus Brooks, 57, Barton Arcade, Manchester.

SHUTTERS.—No. 25,513. Improvements in photographic shutters. Jules Richard, 53, Chancery Lane, London.

POSTCARDS, ETC.—No. 25,580. Improvements in and relating to photographic pictures or greeting cards and the like. Julian Athelstan Tayler and Ernest Percy White Tayler, 12, Cavendish Avenue, New Malden, Surrey.

CINEMATOPHGRAPHS.—No. 25,666. Improvements in safety devices to prevent the spread of fire when a cinematograph film is ignited. Leo Kamm, 27, Powell Street, Goswell Road, London.

### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

NON-HALATION PLATES.—No. 11,341, 1908.—The invention consists in the coating of gelatine or other emulsion on plates of coloured glass, celluloid, etc., with the object of preventing halation in the negatives. The use of chromium-green glass is specially mentioned, and a modification of the method consists in the addition of chromic salts, such as the oxide, or hydroxide, or chrome green, to the emulsion. The inventors cite, as an advantage of the process, the fact of the green glass or film of the negative causing increase of brilliancy in prints from flat negatives and, further state that "even in the case of an ordinary negative these plates enable the printing to be done in a very bright light, which otherwise would injuriously affect the character of the picture to be produced, considerable time being thus saved." Bremer Trockenplattenfabrik B. Klatte, Bremen, Germany.

REPAIRING CINEMATOPHGRAPH FILMS.—No. 16,115, 1908. The process consists in treating cinematograph films which have become scratched, or have lost their polish in use by a method which restores to a great extent their transparency.

For effecting such enamelling of films made with gun-cotton, collodion, or celluloid, a very thin layer of collodion, *b*, is spread on a perfectly polished surface, *a*, of great length, such as plate glass, a table, a waxed cloth, glazed paper or cardboard, etc. The cinematograph film *c* to be regenerated is then unwound and placed on the collodion surface, so that the side not carrying the image is in contact with the collodion. As the unwound band *c* is being applied to the collodion surface *b*, some solvent for the substance

constituting the support or film (acetone, amyl acetate, alcohol, ether, methyl alcohol, etc.) is applied by means of a suitable device—for instance a bottle *d* and pipe, in such a manner that the solvent forms a connection, and acts by its interposition as a cement between the band *c* and the collodion layer *b* on the polished surface. A roller, *f*, operated mechanically or by hand, is arranged so as to press on the band *c*, thereby expelling the excess of solvent as well as air-bubbles, and pressing the band *c* firmly in contact with collodion layer *b*. When the band *c* has been properly applied and cemented, it is left to dry, and then, as in the usual enamelling process, the collodion layer *b* is cut through on both sides of the band *c*, which is then detached by stripping it off the polished surface *a*, which retains the remainder of the collodion layer *b* previously spread on it. The band *c* thus treated has thus a fresh polished surface, while the enamelling thus effected causes to disappear, or greatly reduces, all the existing defects. A similar operation can be effected on the emulsion side of the band in order to remove, repair, or fill up its scratched or scraped portions caused by its passage through the apparatus. It is obvious that the above-mentioned method of operating is given merely by way of example, and the glazing could be effected by means of some other regenerating substance than collodion, such as, for instance, gelatine, cellulose salts, varnish, casein, etc. La Société Anonyme des Plaques et Papiers Photographiques, A. Lumière et ses Fils, 287, Cours Gambetta, Lyons, France.

TELEGRAPHIC TRANSMISSION OF PHOTOGRAPHS.—No. 16,272. 1908. The invention is an improvement of that described in specification No. 1,615, 1908, according to which the differences in the relief of the image to be transmitted are translated into variations of electric intensity by an arrangement which has the great advantage

Fig. 1.

of being mathematically exact, but has, on the other hand, the drawback of requiring the use of a mechanical arrangement having a certain inertia, not to speak of the vibrations to which it is

subject, more particularly after a sudden change in the relief. It results from the foregoing that the speed of working of apparatus arranged on the lines set forth in the specification of Patent No. 1,615, 1908, is limited.

It is proposed to remedy this drawback by substituting for the arrangement of rheostat at the transmitting station a microphone, by the intermediary of which the variations of electric intensity are produced in the line circuit by the differences of relief of the various portions of the tracing or the image to be transmitted. In the accompanying drawings Fig. 1 shows the arrangement of the transmitting station A employing a microphone 18.

The relief proof 1 is still mounted on a cylinder 2, having a rotary motion around a fixed screw 3, which ensures at the same time its displacement parallel with its axis. Opposite the cylinder 2 a stylus 4, fixed to the end of a flexible strip 4', is provided. The stylus 4 is regulated in such a way as to be always in contact, on the one hand, with the proof 1, and, on the other hand, with the diaphragm of the microphone 18, which latter is rigidly mounted opposite the movable cylinder 2.

It is evident that the differences of relief of the different portions of the proof 1 will produce a more or less energetic pressure of the stylus 4 on the diaphragm of the microphone 18, and that this latter, pressing more or less strongly on the granules, will allow a quantity of current to pass from one of its terminals 8<sup>1</sup> to the

Fig. 3.

Fig. 2.

other 8<sup>2</sup>, which quantity consequently varies with the degree of the relief of the proof 1. The current of variable intensity passing through the microphone 18 acts on the transmitting station B at a distance in the manner indicated.

The following description of this microphone will further show how the other conditions, which are held to be indispensable for its application to the telestereograph, are realised.

This microphone with carbon granules is a so-called "separate granule" apparatus. It is formed of a cylindrical metal box *a*, in which a carbon bottom plate *c* is mounted with the interposition of an insulating ring *b*. On this bottom plate *c* there is fixed a thin insulating plate *d* of about 1.5 millimetres in thickness and perforated with circular holes *e*, which are themselves equidistant from each other and arranged in three concentric equidistant rings. In each of these holes, the diameter of which is about 2.5 millimetres, a spherical granule *f* of carbon is located, being itself, for instance, two millimetres in diameter.

The microphonic diaphragm *g*, mounted opposite the granules *f*, may be formed either of a disc of carbon of suitable thickness, or of a plate of steel or silver, or any other suitable metal. It is firmly gripped at the edge between a felt washer *h* and the ring *i*, which places it in direct connection with the body of the box *a*; 8<sup>1</sup> and 8<sup>2</sup> are terminals bringing the current. The apparatus is regulated, and the position of the origin of the galvanometer deflections and the required degree of sensitiveness obtained, by inserting one or more paper or thin cardboard washers *l* between the felt *h* and the diaphragm *g*. It is interesting to note that firm gripping of

the edge of the diaphragm *g* is necessary in order to exactly determine its position relative to the bottom plate *c*.

The working of the microphone constructed in the manner hereinbefore set forth, is evidently the same in all the positions which it is possible to give to this apparatus.

If the space between the diaphragm *g* and the bottom plate *c* is greater than two millimetres, the granules *f*, which, according to the preceding indications, are two millimetres in diameter, are normally in contact with only one of these elements, and the electric circuit is broken. This circuit only closes if there be exerted on the diaphragm *g* sufficient pressure to bring the granules *f* both in contact with the diaphragm *g* and with the plate *c* simultaneously. Under these conditions, when the apparatus is at rest, a galvanometer connected with the line, will indicate no deviation. There would be, however, a sudden deviation when a pressure is exerted on the diaphragm *g*, and as the strength of this pressure may be regulated, as hereinbefore set forth, by means of paper washers *l*, it is this first arrangement which is the best for the transmission of writing and line drawings.

If the space between the diaphragm *g* and the bottom plate *c* is not greater than two millimetres, the origin of the deviations is no longer the zero of the galvanometer, but a point which may be selected by regulation, seeing that current is always passing through the microphone. This arrangement is the most practical for the transmission of images with half-tones. Edouard Belin, 2, Rue Poncelet, Paris.

**TELEGRAPHIC TRANSMISSION OF PHOTOGRAPHS.**—No. 1,203, 1903. The invention relates to an improved means for transmitting photographs, etc., from one place to another by telegraphic means, the objects being to facilitate the conversion of the photograph to cypher, transmissible as an ordinary cypher telegram, and its reconversion at the receiving station to a facsimile of the original.

A transparent barrel revolves in a close spiral and contains within itself a suitably constructed electric lamp. The barrel is mounted at each end in such a manner that a transparent photographic film may be readily affixed to or removed from it, and is contained in a compartment, light-tight save for a small aperture equal in diameter to the pitch of the spiral. Light admitted through this aperture is concentrated upon a selenium cell contained in a second compartment, which cell forms part of an electric circuit, the rays of light varying in intensity according to the density of the portions of the film successively presented to the aperture. Sympathetic variations in the current are thus established which deflect the needle of a galvanometer, hereinafter called the shutter, constructed in such a manner as to cover and uncover one or two of three pin-holes communicating with a third compartment. These pin-holes are arranged in a line equidistant from one another, and admit to a third compartment light from a lamp arranged in the second. A small drum within the third compartment geared to a clockwork or other motor which imparts motion to the barrel, presents a sensitive photographic ribbon to the pin-holes, which ribbon, being acted on by re-agents, will exhibit single or double lines of varying lengths traced thereon accordingly as the movements of the shutter have regulated the admission of light, the ribbon being graduated in sections corresponding proportionately to the distance moved by a point on the periphery of the barrel in one revolution, and these sections are again sub-divided proportionately to the horizontal traverse of the point during the same period. The three distinct signatures registered on the ribbon may be denoted for the purposes of transmission by a convenient cypher consisting of numbers or letters of the alphabet, the length and position of the signature determining the particular number or letter to be used. The various parts of the apparatus are isolated in light-tight compartments. The cypher having been transmitted and received, may be reconverted to pictorial form by means of an instrument operated by three keys actuating levers armed at their extremities with suitable type, producing three distinct impressions, the type all acting at one point. Each of the keys when depressed imparts motion, by means of ratchet and pawl, to a cylinder which is constrained to move in a spiral, both rotary and translative motion being proportionate to the corresponding motions of the barrel. The type corresponding to the key depressed makes a distinctive impression upon a transparent film faced with a suitable opaque substance readily removable by the type. A

graduated indicator is fitted to the apparatus so that the exact position of the cylinder in the course of its rotation can always be seen. Frank Wyndham, 11, Grosvenor Road, Norwich.

## New Trade Names.

**CERTINAL.**—No. 307,396.—Chemical substances used in photography. Ilford, Ltd., Britannia Works, Roden Street, Ilford, London, E., manufacturers of photographic plates, papers, and films, October 28, 1908.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

FRIDAY, DECEMBER 11.

Colne Camera Club. "On the Printing, Developing, and Toning of Velox Papers." W. F. Slater.  
Whitby Camera Club. Dutch Lantern Pictures. A. E. Staley & Co.

MONDAY, DECEMBER 14.

South London Photographic Society. "Bromide Printing and Toning." E. W. Taylor.  
Scarborough and District Photographic Society. "Pictorial Slides and Bromide Prints." Harry and C. E. Wanless.  
Cleveland Camera Club. "On the Printing, Developing, and Toning of Velox Papers." W. F. Slater.  
Handsworth Photographic Society. Conversatione.  
Lancaster Photographic Society. "Making, Mounting, and Binding of Lantern Slides." R. T. Simpson.  
Bradford Photographic Society. "Lantern Slide Making." F. Nicholson.  
Southampton Camera Club. "The Humble Beauties of the Flower World." E. Seymour.  
Gravesend Photographic Society. "The Possibility of a Photograph being Artistic." Edgar F. Simons.

TUESDAY, DECEMBER 15.

Royal Photographic Society. Technical Meeting.  
Darlington Camera Club. "On the Printing, Developing, and Toning of Velox Papers." W. F. Slater.  
Hackney Photographic Society. Members' Annual Sale.  
Epsom and District Literary and Scientific Society. "Architectural Photography, Pictorial and Technical." H. W. Bennett, F.R.P.S.  
Leeds Photographic Society. "The Elements of Architectural Photography." J. R. Wigfull.  
Birmingham Photographic Society. Lantern Evening.  
Blackburn and District Camera Club. "Photography in Natural Colours." F. Higginbottom.  
Worthing Camera Club. "Carbon" Demonstrated. Richard Long.  
Wimbleton and District Camera Club. Discussion on "Lantern Slide Making."  
Hanley Photographic Society. Y.M.C.A. Trimming and Mounting Competition.  
Chiswick Camera Club. Lantern Lecturettes. By members.

WEDNESDAY, DECEMBER 16.

South Suburban Photographic Society. Discussion. "The Best Way for Beginners?"  
Wimbledon Park Photographic Society. "Transparencies, How to Make and Colour Them." Howden Wilkie.  
Borough Polytechnic Photographic Society. Lantern Slide Competition.  
Croydon Camera Club. "X-Ray Work." C. E. Kenneth Mees, D.Sc. and W. H. Smith.  
Dudley and District Camera Club. "On the Printing, Developing, and Toning of Velox Papers." W. F. Slater.  
North Middlessex Photographic Society. "Elementary Optics." H. Stuart.  
Leeds Camera Club. "Leeds in the Olden Days." Alf Mattison.  
Coves Camera Club. Lantern Slide Making Competition.

THURSDAY, DECEMBER 17.

Birmingham Photographic Society. "Flashlight Photography with Agfa Specialties." F. C. Hart.  
Bolton Amateur Photographic Society. Exhibition of Thornton-Pickard Prize Slides and Apparatus. R. Hesketh.  
Leek Photographic Society. "A Scamper in Holland." Zealand S. Coy.  
Handsworth Photographic Society. "Agfa" Chemicals and their Application." F. C. Hart.  
Liverpool Amateur Photographic Association. Smoking Social in Club Rooms.  
Midcheshire Photographic Association. "Printing Processes: Oil and Gum." T. A. Knoblauch and Robert Thomson.  
Richmond Camera Club. "Mounting and Framing." J. D. Gibson.  
Jarrow Mechanics Institute Camera Club. "On the Printing, Developing, and Toning of Velox Papers." W. F. Slater.  
L.C.C. School of Photo-Engraving, Bolt Court. "The Mark-Smith Etching Machine." G. Venner Dear.

### ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held November 8, the President, Mr. J. C. S. Mummery, in the chair. On the proposition of Mr. A. W. W. Bartlett, seconded by the Rev. F. C. Lambert, Messrs. Calder, Marshall, and Co., were re-elected auditors for the society.

The following were elected Fellows:—Lord Redesdale, C.B., C.V.O., J.P., D.L., Nicholas Smirnoff, H. Essenhigh Corke, H. G. Drake-Brockman, and Mrs. Miuna Keene.

The President, Mr J. C. S. Mummery, then delivered his presidential address on the "Place of Photography among the Graphic Arts." Photography, he said, had had a very great destroying effect. It had no doubt reflected the spirit of the age which gave it birth, an age of commercialism. Its triumphs had been those of commercialism rather than of improvement upon the arts which had preceded it. But in art, the mental aspirations were towards the best, in however small volume, rather than towards a great deal of only mediocre quality. Also when photography came into existence art in England was at a low ebb. The exponents of the art of painting aimed at telling a story or pointing a moral, not at following art for art's sake. There were some few great exceptions who have since been recognised as masters of art; but at the time they were not understood, and the general mass of work was weak in kind. It was for this reason that at first photography was spoken of as a possible displacer of painting; whereas painting, of all the arts, has been the least affected by it. Only the lowest forms of portrait painting could be said to have been affected by photography.

Apropos of the reference to the early days of photography, it was an interesting question—though the speaker could only put the question—whether the Pre-Raphaelite movement in art was in any way inspired by photography. If it was not, it was remarkable that, within a few years of Daguerre's discovery becoming known, a school of painters should have arisen whose tenets were opposed to the "breadth" then common in painting, and in favour of almost photographic detail.

Another destroying act of photography was committed upon miniature painting. The modern effort to revive the art of the miniature painter had been sustained, but the result, the speaker thought, could usually be described as not that of the miniature painter, but only painting on a small scale.

As regards copper-plate engraving, which about the middle of the last century was a highly developed art, but more in a reproductive than in a creative way, attempts to quicken and cheapen it had undoubtedly destroyed it. It was in its sphere an example of beautiful individual treatment; but its sister arts of mezzotint and etching, because they were practised as ends in themselves, possessed greater vitality, and were less readily spoiled by photography. Line engraving, too, fell into desuetude from want of patronage, and was thus dead in England; whilst wood engraving, though a superb art, was reproductive chiefly, and was thus killed by competition with photography, except in its commercial applications. At the present time there was no school for the training of the wood-engraver, and no artist in England who practised the art.

Turning to the estimation in which objects of art are held at the present day, Mr. Mummery said that the plethora of cheap productions had undoubtedly discouraged the collector, who in former days had sought to possess himself of objects for their beauty, not for their rarity or uniqueness. He could hardly believe that collectors could possibly take pleasure in the acquirement of process reproductions, yet an item in a recent sale catalogue suggested that even that might come. The item was a set of 1,623 postcard portraits of Phyllis and Zena Dare, unused, all different, and worth £14. He had inspected all the cards and had found that, in fact, many were identical in subject—the same smile in a different setting. It appeared that one of the beneficent duties which may save the work of the camera from being described, in Landseer's punning phrase, the "Foe to Graphic Art," was its service in transferring a knowledge of art from the classes to the masses. It might thus raise public taste and make the way for the artists in photography; but it had still to be admitted that the latter were uncertain in their aims, and ran after strange devices, which they mistook for or asked others to accept as art.

Mr. J. C. Warburg, in proposing a vote of thanks to Mr. Mummery, mentioned that, in reference to photography and the Pre-Raphaelites, Mrs. Cameron was the photographer of pictorial aims in that period, and he believed she was more influenced by the Pre-Raphaelites than they were by her.

The vote of thanks was seconded by Mr. W. Thomas, who said he did so with very great pleasure, since he had had occasion, with other friends in the past, to know, as perhaps others had done no less, the endless labours which Mr. Mummery had performed with the aim of advancing pictorial photography.

With the demonstration of the meeting's thanks to Mr. Mummery the proceedings terminated.

**SIDCUP CAMERA CLUB.**—The first meeting of the newly-formed camera club, the photographic section of the Sidcup Literary and Scientific Society, was held at the Public Hall, Sidcup, on December 4, when Mr. F. C. Starnes, of Dartford, lectured on "Development." The lecturer dealt fully with the theory and history of developing plates, papers, and lantern slides, illustrating various points by means of excellent lantern slides. Mr. Starnes spoke highly in favour of the Watkins' system of developing, and strongly recommended the following formula for developing P.O.P.:—

Metol .....	7 grains.
Tartaric acid.....	58 grains.
Soda citrate .....	35 grains.
Water .....	20 ounces.

The partially printed P.O.P. print is placed in the above dry as it comes from the frame, and is developed to its full strength; it is then toned in the usual manner and fixed. If a print of a reddish tone is required, the picture need not be toned, but simply fixed. The officers of this new and promising club are: President, F. H. Carr, F.I.C.; vice-presidents, B. Davidson and Harold Moore; hon. secretary, H. B. Hale, Gresham Lodge, Station Road, Sidcup. The meetings are held monthly, the next being on Tuesday, January 26, when Mr. P. R. Salmon will lecture on "Home Portraiture." The annual subscription is 5s., but members of the Literary and Scientific Society can join on the payment of half a crown.

**BOROUGH POLYTECHNIC PHOTOGRAPHIC SOCIETY.**—At the meeting held December 2, Mr. Essinghish Corke gave the lecture on "Various and Novel Lighting Effects," which he has delivered before a number of photographic societies during the present season. In this lecture he has explained and illustrated on the lantern screen a variety of effects in portrait lighting, produced in most cases by methods devised by himself, and giving the effects of various forms of artificial lighting by the use of daylight in an ordinary room. The lecture has thus been one of the most novel at present offered to photographic societies, and it may therefore be opportune to say that the lecturer, who follows the profession of a portrait photographer at Sevenoaks, Kent, has still one or two open dates among societies within a reasonable distance of London, whilst he hopes shortly to arrange visits to a series of the photographic associations in the North of England. Mr. Corke prefaced his lecture with some general elementary instruction on the taking of portraits in an ordinary room with no accessories beyond an extemporised background and a reflector. He then proceeded to show examples of modifications in outdoor and indoor portraiture, and to explain the method employed in producing them. One of the first of these was a portrait in the style of a pencil sketch. For this purpose the model was posed out of doors against a dead white background and in a full flood of light on all sides. The face was arranged in profile, and a dead black screen placed close up to the face, so as to cause the outline of the face to appear as a darker line than the rest of the face. A rather over-exposed negative was made and kept thin and flat in development. The effect thus obtained is heightened by covering the back of the negative with matt varnish, and putting light washes of colour on those parts which print too darkly, such as the hair and the shadows under the nose and chin. Very delicate and dainty effects were secured by this method.

A series of striking effects obtainable by using only a small area of light from a window in conjunction with a mirror in the room were shown, and the method of each explained.

The latter portion of the lecture dealt with the method of firelight and lamplight effects, which have already been described and illustrated in the Press, so that a detailed report of them is not necessary. The method, in brief, consists in photographing the sitter by a strong light coming through an aperture at the floor level, keeping the negative fairly strong, and making a print the whole ground of which is pale orange in colour. Mr. Corke made his prints in carbon on orange-coloured transfer paper, or prepared bromides, which he stained with the "Bertha Orange" dye of the Vanguard Manufacturing Company. The method in the case of photographs giving the effect of lamplight portraits was very similar.

The lecture, which was illustrated by a series of fifty slides, was listened to with great interest, and has evidently interested photographers in a novel and very fascinating sphere of work.

## New Materials, &c.

"Ensyna" Paper. Made by Houghtons Ltd, 88 and 89, High Holborn, London, W.C.

Under the name "Ensyna" simply, and without further qualification, Messrs. Houghtons Ltd. have introduced a new printing paper, which they are wise not to have named in any way which can suggest resemblance to any other sensitive paper. For "Ensyna" is a product totally different from any other on the market: different in the substances contained in its sensitive film; different in the means and method taken to produce the picture upon it, and different in the possibility of modifying the standard procedure to secure special effects. Though "gaslight" describes Ensyna in so far as the paper may be exposed and developed by gaslight, the new product is totally unlike the many papers now termed "gaslight," and the developer used for them would be quite useless for "Ensyna." To sum up, in a word, the distinctive quality of the new paper with a view to its intelligent use, "Ensyna" is a silver paper, an invisible image on which is built up by an acid or physical developer, that is to say, the difference between the present dry plate and the defunct wet collodion process is no greater than that between "Ensyna" and "gaslight" or P.O.P. papers.

And as regards the practical facilities which this new method provides, it may be said that "Ensyna" gives the effects of P.O.P. (in a more permanent form) by the "gaslight" method. But as it is much more rapidly finished off than a gaslight paper, and as it dispenses with gold or platinum toning, it is more to the point to say that it gives by gaslight prints which resemble (but have greater claims to permanence than) those on self-toning papers, by a method of production which is as expeditious as the "development" and clearing of platinotype prints. In other words, "Ensyna" paper allows a photographer to make by his fireside of an evening prints which have all the appearance of toned or self-toned P.O.P.'s, and are turned out with an interval of less than ten minutes between exposing behind the negative and hanging up to dry. These claims can be substantiated by the expenditure of a shilling on a packet of paper and the necessary developer; but before these materials are taken into use there are other points in the use of the paper which should be noted also for the confirmation which can easily be applied.

It should first be explained that the procedure in the case of "Ensyna" paper is as follows:—

Exposure .....	say 0 min. 30 sec.
Water bath .....	say 1 min. 0 sec.
Development .....	say 2 min. 0 sec.
Fixing .....	say 0 min. 30 sec.
Washing .....	say 2 min. 0 sec.
Total .....	6 min. 0 sec.

Unlike other printing processes, in which an alkaline developer is used, increase in the time of exposure of "Ensyna," even up to many times the amount required for a normal print, has only one result, that is to give a print of a warmer colour. In the other direction—of under-exposure—there is not the same range; a print which is much under-exposed is fogged by the developer before it gains proper strength, but if, despite this fact, the process be carried on and the fogged print be treated with Farmer's reducer a good print can nevertheless be obtained. In short, the novel fact to be borne in mind in connection with "Ensyna" paper is that the tone of the print is fixed by the exposure, and that within very wide limits errors of exposure do not mean the failure to obtain a print, but have as their effect the production of prints warmer or colder in tone than was intended.

Further, it will be understood that the above method gives a print consisting of a pure silver image, and therefore the permanence of "Ensyna" prints is at any rate equal to that of bromides, leaving out of consideration the fact that its sensitive film is of a much more soluble character, and allows of very rapid fixation in a much weaker solution of hypo than the one ordinarily employed. The above observations indicate the salient points of difference between "Ensyna" and other papers which are currently employed. It now remains to describe the results obtainable with the new paper and

the materials offered by Messrs. Houghtons Ltd. for development and fixing.

Though "Ensyna" is capable of giving a wide range of tones, it will be used—particularly by professional and trade workers—as a means of obtaining prints resembling sulphocyanide-toned P.O.P.'s and self-toning results. That it does give prints which are practically indistinguishable from these was evident to us by our first trials of the paper. The tone depends, as already stated, on the adjustment of the exposure, and the time that is necessary for the purplish-black characteristic of a P.O.P. print toned in a gold-sulphocyanide bath is somewhere about the minimum which the paper should have. Exposure much less than this leads, as we have said, to fogged prints which require cleaning in Farmer's reducer. In the direction, however, of over-exposure, the paper will stand a good deal more than can possibly be given to it unintentionally, and the only effect is to give prints of a warmer colour, and in regard to all these processes it should be understood that the image, necessarily from its method of formation, consists of pure silver deposited in various states division which give the different tones. The theory of the process thus supplies the strongest *a priori* reason for regarding the "Ensyna" results as permanent.

This question of permanence will at once arise in connection with the makers' directions to fix for half a minute only and wash for two minutes only. Those who would hastily condemn this recommendation as dangerously heterodox should not overlook the fact that the substance of the sensitive emulsion is not silver bromide, but a silver salt of much higher solubility, and therefore that such a short time of fixation as half a minute may conceivably be ample for the complete conversion of the silver salt into perfectly soluble compounds. And further, the other fact that must not be disregarded is that the image is not one readily affected by traces of hypo left in the film. The makers, we imagine, will not claim that two minutes completely discharges the last traces of hypo from a sheet of paper. But what they do claim, and have proved by repeated practical tests, is that the silver image produced by the "Ensyna" method possesses a degree of immunity to the action of hypo such that the minute traces left after two minutes' washing have no prejudicial effect upon the print. And as it is common knowledge that the first short period of the washing process removes over 90 per cent. of the hypo, and as it has further been proved repeatedly that a developed bromide (i.e., silver) print will last indefinitely, even when it has received the briefest rinse from the hypo bath, therefore, say we, it is reasonable to confirm the correctness of the view taken by the makers, pending the opportunity for practical trials. Simple dipping of part of a sheet of "Ensyna" paper into the hypo bath will show the great speed at which fixation takes place, a fact which should provide reassurances as to the like effectiveness of the rapid washing.

It has been necessary for us to touch upon these points at some length, since the instructions for the use of "Ensyna" differ so greatly from those for other papers. Indeed, they differ more than is apparent from the makers' directions, yet the provisions made by Messrs. Houghtons for all classes of users have reduced the manipulation of the paper to the acme of simplicity. The print, either at once after exposure or after the lapse of any reasonable time, is covered with clean water, in which it remains for a few seconds—until it becomes limp. The water is then poured off and sufficient developing solution for the single print applied—i.e.,  $\frac{1}{2}$  oz. for prints up to 5 x 4, and  $\frac{3}{4}$  oz. for prints up to half-plate. After development to a point a little short of full—which lasts about two minutes—the developer is thrown away, clean water poured on, and the print allowed to reach its full strength. It is then transferred to the hypo for half a minute, and then given its washing of two minutes, or longer if more convenient.

Thus the materials for the process other than the paper are the developer and the fixing-bath. The former, which has to be of composition specially suited to the process, is put up by Messrs. Houghtons as "Ensynoid," both as a single solution sufficient to make 24 ounces of developer for 6d., or as compressed tablets ("Ensynoids") packed in tubes, containing 1 doz. pairs (each of which makes 8 oz. of developer) at a price of 1s. 6d. These "Ensynoids" are likewise supplied in cachets containing one pair of tubes (8 oz. of developer) for 2d. per cachet; and the developer is also supplied in large quantities to professional and trade workers on special terms. The "Ensyna" acid fixing salt, which is specially recommended for

the process, and certainly dissolves most rapidly, is sold in tins sufficient to make 60 oz. of fixing solution for 3d. The tin is marked so that one-third only of the contents can be used at a time to make 20 oz. of the bath.

The paper is sold in sheets  $24\frac{1}{2} \times 17$  at 2s. 6d. per tube of two sheets, or 13s. 6d. for 12 sheets. The gross packet of quarter-plate pieces is sold at 6s.;  $6 \times 4$  at 9s. 4d.; and  $8 \times 6$  at 18s. 6d. "Ensyna" is, of course, put up in 6d. and 1s. packets—e.g., 22 quarter-plate pieces,  $16 \times 5 \times 4$ , or 10 half-plate pieces for 1s. Long as this notice has already proved, we have not yet exhausted what we have to say on this remarkable addition to photographic printing processes, and we shall have to return to the subject at an early opportunity. Nevertheless, we have said enough to show that the trade worker, no less than the amateur, has here the means of producing with great expedition prints of undoubted permanence, and that, under conditions which render him independent of daylight. We anticipate that the forthcoming Christmas season will see our amateur friends busy with trials of the new paper, and it is not too much to suppose that even now the busy professional may be glad to avail himself of the aid of "Ensyna" in dealing with a press of work, or will certainly lose no time in fully investigating its remarkable properties.

**DEVELOPER PRICES.**—Messrs. Fuerst Bros. advise us that from January 1 next the prices for the Pushaxe Universal Developer will be as follows:— $\frac{3}{4}$  oz. bottles, 1s. 2d. each; 7 oz. bottles, 1s. 10d.; 18 oz. bottles, 3s. 3d. Also from January 1 the following reductions in the price of Hauff's well-known cartridge developers, amidol, metol, glycin and ortol, will be in force: 1s. 10d. per box of six cartridges, and 3s. per box of ten cartridges.

## New Apparatus, &c.

THE "AUTOKON" ENLARGER. Messrs. Griffin, of Kingsway, London, W.C., have issued an improved form of the automatic enlarging outfit, which, as our readers know, obviates the separate focussing of each enlargement, the only adjustment necessary being that for the size of the picture, which is done by means of the rack and pinion. In the improved form, a double swing is given to the easel with a view to correcting distorted lines in the negative. Further,

the baseboard is provided with such length of rack work as is sufficient for making a lantern slide from a quarter-plate negative, for which purpose the lantern is employed as a camera, an additional carrier replacing that for the negative and carrying a sensitive lantern plate, whilst the easel has a detachable board, in which the negative is placed. Also, the enlarger is now made throughout in mahogany, although its price has not been raised. Complete with  $5\frac{1}{4}$ -inch condenser, oil or incandescent gas lamp, lens, easel, carriers, and baseboard, the price is £5 in quarter-plate size, or £3 5s. without condenser and lamp. The whole apparatus folds up and packs into a case measuring  $17 \times 18 \times 16$  inches.

## Analecta.

*Extracts from our weekly and monthly contemporaries.*

### Tank Development of Lantern Slides.

Mr. S. E. Dowdy, writing on the subject of "tank development for glass positives and lantern plates" in "The Amateur Photographer and Photographic News" for December 8, says: "The tank method is peculiarly well adapted for this purpose if a systematic way of working be adopted. Briefly, its advantages over the usual way of doing slides singly in a dish may be enumerated as follows: In the first place, it reduces the process of obtaining a set of slides of similar density and tone to almost a mechanical certainty. Secondly, it admits of the prolonged use of very dilute developers, such as occasionally have to be used to obtain very warm tones, without fear of oxidation of the solution and staining of the slides. Again, the dilute developers generally used in the tank yield softer effects, and bring out fine detail better than the stronger solutions more often employed in dish development. It is also at times a great advantage to be able to develop a batch of exposed slides and at the same time attend to something else."

## New Books.

"The Wellcome Photographic Exposure Record and Diary." London: Burroughs, Wellcome, and Co. 1s.

Of improvement in outward form and internal arrangement of this pocket-book we can expect to see little sign—Messrs. Burroughs Wellcome have surely touched finality in these respects. But the "Diary," nevertheless, has been further "improved," first by the inclusion of a table of speeds of bromide papers and lantern plates, and, secondly, in an article on time, tank, or stand development, in connection with which a wall chart is presented, giving the times for development of the "average" plate or film, at a series of different temperatures, which table is used in conjunction with a series of factors for plates which are more or less abnormal in reference to Messrs. Burroughs Wellcome's standard of time of development. For the convenience of users in different parts of the world three editions are issued:—1. The Northern Hemisphere Edition (bound in light green), for all countries north of the Tropic of Cancer. 2. The Southern Hemisphere and Tropical Edition (bound in dark green), for all countries south of the Tropic of Cancer. 3. The United States Edition (bound in red), for use in the United States of America. When purchasing care should be taken to specify which edition is required.

"General and Practical Optics." By Lionel Lawrence, London: The Orthos Press.

This book is evidently intended for the use of the sight-testing optician, and therefore it contains very little that is of any interest to the photographer, unless we assume that those interested in photographic optics are of necessity interested in the more general aspects of the science of optics. There are certain references to the "Unifocal" lens, which we may assume to mean the unifocal lens of Steinheil, and the telephoto lens and the stereoscope are described in brief paragraphs. One unfortunate paragraph is devoted to an absolutely wrong description of the Adon lens, which is not an ordinary telephoto construction reversed end for end as the author seems to imagine. Evidently the writer is more at home in the domain of spectacles than of photographic optics, and it is quite possible that sight-testing opticians may find his book to be of very considerable value.

THE "NEW ZEALAND ILLUSTRATED."—This Christmas number of the "Weekly Press," Christchurch, New Zealand, reaches us filled from cover to cover with fine half-tone illustrations, many printed in several colours. The whole production, from the photographic exposures to the printed supplement, is the product of the office's own staff, and is one more of the yearly demonstrations which the "Weekly Press" has given of its efficiency in all departments of the reproduction crafts.

## CATALOGUES AND TRADE NOTICES.

**ENLARGING NOTES.**—Messrs. Wellington and Ward have just issued a 52-page booklet in the attractive style of their general handbook to the use of the Wellington products. It deals, however, only with the making of enlargements on the "Wellington" papers by day and artificial light. The writer shows how advantage may be taken of the excellent Wellington S.C.P., or gaslight paper, for enlarging work under suitable conditions, and proceeds to describe the chief forms of apparatus for the making of enlarged prints. Development, toning, and mounting enlargements are the subject of instruction, and there are also useful notes on the printing of clouds into enlargements and the use of locking silk. In short, the matter is nicely adapted to the wants of the amateur worker, who does not require to be confused by an overplus of advice. We advise application for a copy to Elstree, Herts, or to the local dealer, who can adopt no better method of drawing the attention of his customers to the fine products of the Wellington factory.

**CHRISTMAS PRESENTS.**—Private individuals, equally with photographic dealers, may be advised to choose from the catalogues of the photographic houses when making Christmas presents or causing them to be made, and in carrying out this excellent policy, so far as it concerns young folk, one list which should not be overlooked is that of Messrs. W. Butcher and Sons, Limited, entitled "Hobbies for the Boys." This catalogue includes not only magic lantern slides, cinematographs, and enlargers, but model steam engines, locomotives, and electrical and mechanical novelties, suitable for presents. In connection with this and another list specially appropriate to the Christmas-present season, Messrs. Butcher issue a set of window slips, calling attention to the suitability of cameras, etc., as Christmas gifts.

**THE "COMPOUND" SHUTTER.**—Users of this almost ubiquitous shutter, who obtain it without full details as to its use, will be interested to learn that Messrs. A. E. Staley and Co., 19, Thavies Inn, E.C., have just issued a booklet descriptive of the latest model of this excellent piece of mechanism. The booklet can be had by sending Messrs. Staley one penny stamp.

**BARGAINS AT N. AND G.'S.**—A list of sundry apparatus, among which figure a few cameras, has been prepared by Messrs. Newman and Guardia, 90-92, Shaftesbury Avenue, London, W., and is found to offer a variety of goods at very considerable reductions. Printing-frames, changing-bags, trays and dishes, and other articles, for the quality of which the name of Messrs. Newman and Guardia, as vendors, is sufficient guarantee, are listed. The cameras include various special patterns and sizes of the N. and G. instruments, and both amateur and press photographers may be advised to take the opportunity of securing one of these deservedly renowned instruments at a substantial reduction of price—in some cases for less than half the list price.

A FULL descriptive circular of the Ewon Arc Lamp recently noticed in these pages is now obtainable from Messrs. A. E. Staley and Co., 19, Thavies Inn, Holborn Circus, London, E.C.

## News and Notes.

**AN ADON TELE-PHOTOGRAPH.**—Messrs. J. H. Dallmeyer, Ltd., send us an excellent enlargement from a negative taken with a Dallmeyer Adon telephoto lens in 1-50th second on the occasion of Mr. Jabez Woolfe's seventh attempt to swim the Channel. The Adon was used on a 5 x 4 "Videx" camera, the negative being made on a rapid "Imperial" plate. The camera extension was about 41 in., which gave an equivalent focal length of 32½ in. At the time of the exposure the photographer, Mr. Dudley Stone, of St. Bartholomew's Hospital, was about 60 ft. from the swimmer, and the crispness of the definition (the word "Oxo" being readable on the cup, which is being offered to the swimmer) speaks well for the optical quality of the work.

**FIRELIGHT EFFECTS BY DAYLIGHT.**—Those who have read the reports of Mr. Essenhigh Corke's lecture on the methods of firelight-effect photography will be interested to know that a booklet embodying Mr. Corke's instructions, and illustrated by two excellent

examples of his results, is offered free by the Vanguard Manufacturing Company, Maidenhead, who, if specially asked to do so, will at the same time send their full list of chemical specialties for photographers. Both are certainly worth applying for.

**ROYAL INSTITUTION.**—The following are some of the lecture arrangements at the Royal Institution, before Easter:—Professor W. Stirling, a Christmas course of six experimentally illustrated lectures on "The Wheel of Life," adapted to a juvenile auditory; Professor A. A. Macdonell, three lectures on "The Architectural and Sculptural Antiquities of India"; Professor J. O. Arnold, two lectures on "Mysteries of Metals"; Mr. William Archer, two lectures on "The Revival of Modern Drama"; Dr. Hans Gadow, three lectures on "Problems of Geographical Distribution in Mexico"; Mr. A. D. Hall, two lectures on "Recent Advances in Agricultural Science"; Professor G. H. Bryan, two lectures on "Aerial Flight in Theory and Practice"; Professor Sir Hubert von Herkomer, two lectures on (1) "The Critical Faculty," (2) "Sight and Seeing"; and Professor Sir J. J. Thomson, six lectures on "Properties of Matter." The Friday evening meetings will commence on January 22, when Dr. Alfred Russel Wallace will deliver a discourse on "The World of Life: as Visualised and Interpreted by Darwinism." Succeeding discourses will probably be given by Lieut.-Colonel Sir Frederic Nathan, Professor J. G. Frazer, Professor H. A. Wilson, Sir Henry Cunynghame the Right Hon. the Earl of Berkeley, the Right Hon. Viscount Esher, Mr. S. G. Brown, Mr. R. Threlfall, Mr. A. S. Eddington, Professor Sir J. J. Thomson, and other gentlemen.

**FIRE AT ST. BLAZEY.**—A fire occurred last week in the premises of Mr. S. Dalby-Smith, photographer, Station Road, St. Blaze. The large window had been dressed the previous day for the Christmas show, and as Mr. Smith was lighting the gas some material ignited, the flames spreading with alarming rapidity. Help was quickly rendered, and with great promptitude a large quantity of water was poured on the blaze, with the result that the fire was got under in about ten minutes. Damage amounting to about £50 was caused.

**HOUGHTONS' SMOKING CONCERT.**—The Ensign Smoking Concert is a strong annual feature. This year it will be held at the Holborn Restaurant, in the Throne Room, on the evening of Friday, December 18. A particularly strong programme has been arranged—all professional and music-hall performers—and from the programme there is every prospect of the audience thoroughly enjoying themselves. It is not generally known that Messrs. Houghtons are prepared to sell a few tickets to amateur photographers and others who usually attend functions of this sort, but immediate application—and 2s.—should be made to 88, High Holborn, if a ticket is wanted for this year's concert.

**COWES CAMERA CLUB.**—The meetings of this society will in future be held on the second and fourth Wednesdays in each month, October to March, inclusive, and on the first Wednesdays during the months September to April, in each case at 8 p.m. At a recent meeting Mr. E. E. Vincent was re-elected secretary, and all communications should still be addressed to him at 4, High Street, Cowes, I.W. The society proposes holding an open exhibition in February next, particulars of which will be announced later.

**THE LUMIERE NON-INFLAMMABLE CINEMATOGRAF FILM.**—A demonstration which was largely attended by the cinematograph and photographic trade, was given at the Holborn Restaurant on Tuesday last, when Mr. Thos. K. Grant, of the Lumière N.A. Co., introduced the new non-flammable cinematograph film which is now being manufactured by the Lumière firm. Mr. Grant pointed out that instrumental devices only touched half the problem in cinematograph conflagrations; they might prevent ignition of the film in the lantern, but there was the equal danger due to firing of film standing in the projection box. A non-inflammable film was the only preventive of both these possibilities, and he hoped that the demonstration would show that the new Lumière product responded to the requirements of a safe film. Mr. Grant then attempted to set fire to a film with a match, but the material merely crackled without catching fire. Some lengths of film were then projected in an instrument of the Warwick Trading Co. (Mr. Will G. Barker), and the technical excellence of the results were seen. On stopping the machine the only effect upon the film left exposed in the focus of the light was a breaking down of its structure,

causing a kind of efflorescent appearance upon the screen. Mr. Grant stated that the film had neither celluloid nor any kindred substance in its composition, and that the only difference in its handling was the somewhat longer time which was required for drying. In reply to a question, he said that broken film was repaired in the same way as at present, but in place of amyl acetate used for celluloid film a different cementing medium was used.

THE LEVANTINE RIVIERA is the title of a dainty little guide book issued by Messrs. Reynold-Ball's Guides, 27, Chancery Lane, London, W.C. It deals with that portion of the Italian coast from Genoa to Pisa, which has, within the last few years, become increasingly popular, and photographers intending to winter abroad would not easily find a more suitable locality in which to pursue the search for either health or pleasure, combined with photographic picture making. The book contains numerous illustrations from original photographs, together with a quantity of information, both practical and historical in character. The price is 2s. 6d.

## Correspondence.

- \*• Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

### STEREOSCOPIC PROJECTION

To the Editors.

Gentlemen,—With reference to an article in this week's "B.J." re stereoscopic lantern projection, I might say that on November 4 I gave a demonstration before the Ipswich Scientific Society on this subject. The method I employed was as follows:—

I made two ordinary lantern slides, one for the right-hand and one for the left-hand picture. These were then placed in a solution of iodine in potass iodide to convert the silver image into silver iodide. After rinsing in soda sulphite solution they were washed and placed in a solution of dye until the iodide image was stained right through. One slide was dyed in a water solution of rosaniline acetate and the other in a water solution of aniline green. The slides were then washed in soda sulphite solution, which cleared the high-lights, and then fixed in hypo. After washing and drying they were bound together with a cover glass.

Although the dyes are not optically complementary, they gave most excellent results, and the fact that there was a thickness of glass between the two films did not appear to affect the result. For viewing glasses I fixed out some old plates and stained the films red and green with the same dyes employed for the slides. These plates were then cut up into convenient pieces.—Yours faithfully,

HARRY DE BEER,

Hon. Sec. Ipswich Scientific Society.

93, London Road, Ipswich.

### CARBON PRINTING ON IVORY BY SINGLE TRANSFER.

To the Editors.

Gentlemen,—Will you allow me to reassure those photographers who may be inclined to try the single-transfer ivory process described in the "B.J." of November 20, but who might be deterred from doing so by the editorial remarks introducing my article.

In my experience I cannot recall an instance of the image splitting as you suggest, and the adhesion of the carbon image to the surface on which it is developed, even when so "toothless" as polished glass (unless it has been previously waxed or talced), is so well known that any fear of spontaneous separation from the ivory seems to be quite groundless.

On the other hand, I have within the last few weeks known a photographer obliged to reject an ivory double transfer, made by a trade printer, on account of glistening patches, showing want of adhesion. Such patches might, of course, occur in any process if air spaces are negligently left when transferring, or with double transfer if the substratum is too hard or not thick enough.

I forward for your inspection a miniature of Mr. (now Sir) Henry Harben, which was painted over twenty years ago, and in which there is no sign of splitting away, although the surface is here and there a little chafed from having been kept in a drawer with other photographs.

I cannot help thinking that the Editor has been misinformed as to the likelihood of the image splitting off, and perhaps also as to the process being so much known as is suggested.—Yours obediently,

November 30, 1908.

W. E. DEBENHAM

[The print sent by our correspondent shows that in this case the picture, though coloured, has not peeled off. But by gently applying the point of a penknife to a corner of a deep shadow we find the film leaves the ivory readily, showing that there is little adhesion, as was suggested might be the case. With the double-transfer method, as described in the article, October 16, there is no such risk to be anticipated, as the carbon film is firmly cemented to the ivory by warm solution of gelatine. As we said, the single-transfer system was duly tried commercially in the early days of the process and abandoned, for the reason indicated by us. The fact that our correspondent has known of a print produced by the double-transfer method by a trade printer being returned by reason of faulty manipulation simply is merely an instance of the improper working of the process.—Eds. "B.J."]

## Answers to Correspondents.

- \*• All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.
- \*• Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- \*• Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington Street, Strand, London, W.C.
- \*• For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

### PHOTOGRAPHS REGISTERED:—

- C. P. Cameron, 1, Eyre Place, Edinburgh. Photograph of View of New Buildings for the Edinburgh Life Assurance Company, George Street, Edinburgh.
- G. Barnard, 24, St. George's Road, Brighton. Three Photographs of the Rev. E. A. French.
- Ward's Studio, 46, Staines Road, Hounslow, Middlesex. Photograph of Building "Sentinel," and Photograph of Building, "Brigadier-General."
- H. Shaw, Marine Parade, Scarborough. Two Photographs of Miss Adelaide Pankhurst.
- E. Sweetland, 21, High Street, High Wycombe. Two Photographs of Mr. George Wright Arison, M.A. Photograph of the Rev. Wm. Adair Newman Hall. Photograph of the Rev. Ed. Donmett Shaw, M.A.
- W. F. Wilson, 28, Church Street, Saffron Walden. Photograph of the Very Rev. Chas. R. Chase.

Will Mr. D. Burlin kindly send us his present address?

ENLARGING LENS.—I am making some enlargements (23 x 17) from  $\frac{1}{2}$ -plate negatives, and shall be much obliged if you can answer me the following questions:—(1) Is an 8in. condenser large enough for  $\frac{1}{2}$ -plate negatives, as I find the corners considerably cut off? (2) How is it that I cannot get the image sharp all over? If I focus the centre the edges are not sharp, or vice-versâ. (3) Why does a small stop, f/22, cut off and not sharpen up the image? If I use a larger stop I find no difference to not using any stop. I might just mention that I am using a Ross lens (No. 1,284), of short focus, and an 8in. condenser, for which I have had to reduce the negatives to get the full picture, and the light is acetylene gas, four burners, 100 c.p. each, which give good, even illumination. The lens has no stops, so I have made them, and placed first in the hood and then between the lenses, but with no improvement.—H. W.

(1) Eight inches is barely large enough. You should have 8 $\frac{1}{2}$

Try placing the negative closer to the condenser if possible. (2) If negative lens and screen are in alignment, it is evident the lens does not cover the plate completely. It would appear necessary to use one of longer focus. (3) The trouble is due to the use of a lens of too short focus; it would be less marked with a small light, such as the arc. Use a 9in. or 10in. lens, working at  $f/8$ , and your difficulty will disappear.

**COPYRIGHT.**—(1) A very near relative of mine has recently died. I have a photograph taken by a local photographer three or four years ago. Can I legally copy it and supply my relations and friends, some of whom would like to pay for them? I may mention the photographs were paid for in the ordinary way. (2) Can the next-of-kin prevent the photographer from selling them, as no permission has been given?—P.O.P.

(1) Strictly speaking, the right to copy the photograph belonged to the deceased person, and therefore devolves upon his heirs, like other personal estate. Yet in the absence (probable) of registration we doubt if you or anyone else can be prevented from making copies. (2) The deceased, had he been alive, could have prevented the photographer selling copies without his consent, but whether his executors have the same right may be doubtful. Unless the deceased ordered or paid for the portraits being taken, the copyright is vested in the one who did. It would perhaps be better for the executors to register the copyright.

**REFLECTING POWERS.**—(1) What are the proportions of light transmitted and reflected by a 1-16th in. plate-glass reflector, placed at an angle of 45 degrees, behind a lens? (2) Does the thickness of the glass reflector and its distance from the lens affect the amount of light so passed and reflected? (3) Is there any risk of double reflection?—D. Y.

(1) Percentage of light transmitted, 85.5 per cent.; percentage of light reflected at 45 degrees, 14.5 per cent. (2) Neither the thickness of the glass nor its distance from the lens affects the amount of light passed or reflected. (3) Unless the glass is specially chosen not to give double reflection, it will give it. It can be avoided for average work by having a very thin sheet of glass of perfectly plane surface, but slightly wedge shaped, so as to make the two reflections from front and back surfaces coincide.

**OPALINES.**—Would you please let me know the kind of paper (opalines on glass) to use, P.O.P. glossy or bromides, how to prepare the print for putting on glass, and how to prepare the glass? I think it is with a kind of warm gelatine, and should be greatly obliged. After the print is dry on the glass, can it be fixed to strut back with glue —OPALINE.

The method is given in the "Almanac" just issued, page 821. A quite thin solution of gelatine is made, and print and glass immersed in it, removed together, and squeezed into contact with a flat rubber squeegee. Glossy P.O.P. is generally used for opalines, and in the case of some papers (those of not too hard a film) the gelatine solution is not necessary. But in this case the prints must not be allowed to dry before squeegeeing. In the case of bromide papers, either matt or glossy, the gelatine solution should preferably be used. The strutted back is applied, when the print is nearly or almost dry, with a strong mountant such as hot glue.

**FOCAL-PLANE SHUTTER, ETC.**—(1) With a  $\frac{1}{4}$ -plate focal-plane shutter, with spring at lowest tension, what width of slit would give approximately equal exposure to 1-15 and 1-45 of a second on a behind lens roller blind shutter? (2) In the three-colour carbon process, is there any reason why the colours follow yellow, blue, red?—TANCOLOUR.

(1) Impossible to say precisely, since the slit-aperture is necessarily adjusted to the tension, but the fifteenth of a second is obtained by an aperture the full width of the plate; that for one-fiftieth would thus be about one-third this width. These focal-plane exposures may be said, from the point of efficiency, to be equal to, say, 1-10 and 1-30 with a lens-shutter. (2) The yellow is put down first, as it is the least transparent colour; the red is applied last, as it is the colour which most usually calls for adjustment, and the effect can thus be provisionally tried on the two-colour (greenish) print before finally fixing the last tissue.

**AMIDOL STAINS ON CASHMERE.**—Could you inform me of anything that would remove amidol stains from cream cashmere blouse. It has been washed in the usual way without success.—AMIDOL. Amidol stains are very difficult to remove, and we fear we can-

not suggest any remedy. Your best course would be to send the stained material to the cleaners stating the nature of the stain.

**BROMIDE ENLARGEMENTS.**—(1) For adapting an ordinary projection lantern to bromide enlargement, long streaks appear on the paper as though the light, or rather the fibre of the mantle, is shown, but out of focus. The inverted gas-burner is an improvement, but only slightly. Would bolting silk be a cure, and where should I place it? (2) Also what medium to filter the light to develop by would you advise?—BROMIDE.

(1) It is often difficult to avoid these streaks, but a little adjustment of the light will generally do it with a new mantle. Probably your mantle is an old one in which the threads have become very thin by frequent use. We should try a new mantle in preference to bolting silk. The silk should be in front of the bromide paper, and from half-an-inch to four inches away from it. (2) Two thicknesses of new orange or canary medium will be safe with an ordinary flat-flame gas-burner or oil lamp. With incandescent gas or electric add a sheet of typewriting paper and one or more extra sheets of medium as appears to be necessary. Bromide paper is safe in quite a bright yellow light.

**PORTRAIT LENS.**—I have a portrait lens of the Petzval type, which, when focussed in the camera for distance, measures from plate to stops 7 in. and from plate to back lens 5 in. The diameter of back lens is  $1\frac{1}{8}$  in. The stop marked  $f/4$  is 1 5-16 in. diameter, and  $f/6$  is 1 31-32 in., and so on. (1) Which focus in this type of lens do you take into consideration? (2) Are the stops marked rightly? (3) Do the stops alter in relation to exposure, using it in enlarging as the light passes in the reverse way?—RAMSON.

(1 and 2) We cannot answer either of these questions definitely, because the measurements you give of the stop diameters are obviously wrong. The  $f/6$  stop must be smaller, not larger, than the  $f/4$  stop. You should measure focal length to a point near the stops, and also allow for the fact that the aperture is not the size of the stop, but that of the stop as seen magnified through the front lens. (3) The stops should actually vary when enlarging, practically in the same way as when making a photograph in the camera, but if using a small source of light, exposure need not vary in the same way. You may find that no stop above a certain size affects exposure at all. This is a matter that you must test for yourself. As a rule, the question does not arise, as the same stop can be used for all scales of enlargement.

**DIAMIDOPHENOL FOR BROMIDES.**—Having decided to adopt the diamidophenol developer for bromide work, should esteem it a favour if you would kindly favour me with the following information concerning the working of the same:—(1) Is it really amidol? (2) Is it necessary to rinse in water between developing and fixing? (3) Is it necessary to use an acid fixing-bath? If so, (4) What is the cheapest efficient acid fixing-bath to use? Please give formula. As this developer seems so little known, could you not write up an article dealing with it, or inform me where I can get detailed information concerning it?—H. T. W.

(1) For all practical purposes you can consider it to be the same thing as amidol. (2) With bromide paper you may as well rinse, as there is no necessity to load up the fixing-bath with developer carried over by the prints. Further, if fixing a number of prints in same dish a fresh print filled with developer may cause a stain on the others that it touches. With gaslight paper there is no time for rinsing, and an acid fixing-bath becomes almost necessary. (3) An acid fixing-bath is very desirable, though perhaps not absolutely necessary. It is a great preventative of stains. If, however, you intend to subsequently apply the bromol process to a bromide print it is safer to avoid acid baths and to use plain hypo. In all other cases we should recommend it. (4) The best acid fixer, in our opinion, is, hypo, 4 oz.; potash metabisulphite,  $\frac{1}{2}$  oz.; water, 20 oz. This is, however, not a cheap formula. Perhaps the following will suit you better; Hypo solution (1:5), 5 oz.; soda sulphite solution (1:4),  $\frac{3}{4}$  oz.; tartaric acid solution (1:2), 14 oz. See the "Almanac" for other acid fixers. If you use diamidophenol just as you would use amidol you will find no trouble. The information already published with regard to amidol applies just as fully to diamidophenol.

**STUDIO QUERY.**—Enclosed please find plans of a studio which I have taken. You will see from it that, while I have a good side light,

there is only a small fanlight in the top. There was a top light, the same length as the side light (1ft. 2in.), and right up to the ridge, but it has been taken out, and is on the premises, the roof being now slated with the exception of the fanlight mentioned. The landlord is agreeable to let me put it in again at my own expense. (1) Would it be necessary or advisable to have it put in? The glass is all coated thinly for diffusion, except the three clear panes shown, which I have covered with a linen blind. As the side light faces due south and there is no obstruction to the light, there being no buildings facing (2), would it be advisable to have, say, two large linen blinds (each to cover half), so that we could drop them at will, or please advise us for the best? I am using the "Gladiator" plate, and a lens working at  $f/6$  (Lancaster's £5 10s. Rectograph). (3) Will this give the best work? (4) What colour would you advise me to have the studio papered and painted? I have a large white linen reflector hanging in position 7. It is movable. (5) Will you advise me as to reflectors, and (6) would the angular reflector in Fig. 1 be better than the straight one mentioned and shown in Fig. 2?—W. D.

(1) You do not say the height of the side light, but we think it will be advisable to have some top light, say, half way up to the ridge. (2) Yes. (3) It will certainly produce good pictures, and though not as fast as an ordinary portrait lens, is quite fast enough. A light French grey will be suitable for that aspect. (4) and (5) As the reflector is movable, it can be placed in any position to suit the subject and the light.

**RIGHT TO BUILD.**—May I trespass upon your kindness to advise me on a rather important matter? I have recently taken a twenty-one years' lease of a house, with the intention of building a studio in the rear and carrying on the calling of a photographer, with the full permission of the freeholder, but now find that he is himself under certain restrictions with regard to his conveyance, which contains the following:—"No building shall be erected as a shop, workshop, warehouse, or factory; no trade or manufacture shall be carried on, and no operative machinery be fixed or placed on any lot." We have adjoining us two doctors, a dentist, a veterinary surgeon, and a school of music, all showing boards or brass plates, and we were advised that ours was also a profession, and that the clause in question did not apply. Still, we are very anxious, as the studio is just being completed, and the neighbours seem to be none too friendly disposed. There must have been many similar cases, and if you know of any precedent and what the ruling has been I should esteem it a great favour if you could furnish me with the information.—R. V. HARMAN.

This is a question that we should not like to pass a definite opinion on. It seems that no "building, workshop, etc.," is to be erected on the premises, and the question is, whether a photographic studio is to be considered as a workshop, and whether photography is a trade or not. So far as we can call to mind, it has not been decided in a court of law whether photography is a business or a profession. We think there is little doubt that it would be regarded as a trade.

**FREE PORTRAITS AGAIN.**—A firm solicited orders for free enlargements in this district, and on obtaining them said, of course, they, the receivers, would buy a frame for the wonderful pictures given. To this they agreed. Mouldings were brought for their inspection for the 20 by 16, prices varying from 12s. 6d. to a guinea. They selected the mouldings, but when the frames arrived they were not the ones ordered, the agent stating that they had not quite the same moulding in stock. I may say the frame shown to me could be bought anywhere for 3s. 6d. They had paid deposits varying from 7s. to 17s. 6d., and refused to pay any more. The firm sued them in the County Court, and unfortunately the defendants arrived at court late. The court awarded (on the non-appearance of the defendants) the plaintiffs 2s. per month until the various balances were paid. These people now wish to know what is the best to do in the matter, as they do not wish to lose any more money over the matter, and yet do not feel justified in paying any more to this generous firm.—MAGISTER.

As the people neglected to attend and defend the action, judgment, of course, was given against them, and we expect they will have to pay the sums ordered. They may, however, apply for a fresh hearing of the case, but it is a little doubtful if it will be granted. That seems the only course open to them now.

**BROMIDE.**—Honestly, we do not think it will pay you to manufacture. The only suggestion we can make is that you turn your attention towards the so-called "solar" process, the paper for which is sensitised, by brushing or floating. Formulae recommended for this process have appeared in our columns on several occasions—e.g., January 11, 1907, p. 27, and on March 30, 1906. These latter will be found in the "B.J. Almanac" for 1907, p. 816, and on page 821 of the same "Almanac" are some further formulae for the same process. If, however, you ask us to advise you the best source of information as to the home manufacture of an emulsion paper, we may refer you to "Photographic Papers," by Stiefel, obtainable, we believe, from Messrs. Iliffe, but you must not expect to get a paper equal to the commercial article.

**HYPHO-ELIMINATOR.**—Please give a formula for a cheap chemical which I can use for removing hypo from negatives required to be finished off in a hurry.—SHEPPERTON-ON-THAMES.

Wash the negative for one minute under the tap and transfer to a shallow dish containing water, with enough potash, permanganate in it to turn it pink. Remove the negative as soon as the colour goes, and keep on treating it in the very weak permanganate bath until the colour is not discharged. The negative can thus be made ready for drying within three minutes of coming out of the hypo.

**AEROGRAPH WORK.**—Can you please inform me of any book or article which will serve as an instructor in the use of the air-brush. I have had some experience in working up in black and white, but have not yet had any practice with the aerograph, which I see so often mentioned as essential to those seeking situations.—L. C. F.

A series of articles appeared in the "B.J." during January and February, 1907. They are reprinted by the Aerograph Co., 43, Holborn Viaduct, London, E.C., at a price of 6d.

**TITLES ON NEGATIVES.**—Please can you recommend me an easy method of putting titles on negatives, one that does not require the use of printed type as directed in the "Almanac," section "Negative Varnishes."—W. ESTERHAM.

Reversed rubber stamps for the purpose are sold by Richeford and Co., 8 and 9, Snow Hill, London, E.C.; also, a set of letters, to be attached to the negatives is supplied by O. Sichel and Co., 52, Bunhill Row, E.C., or the titles may be written on transparent tracing paper, retouching medium applied to the part of the negative where the title is to go and the latter laid on, pressed into contact, and a further application of medium given.

**BIRMINGHAM PHOTOGRAPHIC SOCIETY ANNUAL EXHIBITION.**—The Birmingham Exhibition will be held from February 22 to March 6, 1909. Entries close for abroad on January 25, which is also the last day for receiving pictures. For England, entries close February 12, and last day for receiving pictures is February 16. Foreign entries can be forwarded to the Leicester Exhibition (February 11 to 20) previous to showing in Birmingham, and at the close of the B.P.S. show all entries can be sent to the Shropshire Camera Club (March 3 and April 1), if desired. No charge for conveyance between these places will be made.

**\* \* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears on the last portion of the paper.

The Christmas Holidays.—Christmas Day falling on Friday in next week, our readers and advertisers are asked kindly to note that copy intended for insertion in our next issue should reach us not later than Monday or Tuesday morning, as announced in our advertisement pages. The Journal will be published in time for distribution before Christmas Day.

### SUMMARY.

A semi-imaginative account of what takes place when a sitter visits the photographer is given in the shape of a contribution on page 962, entitled "Studio Scenes."

A correspondent on page 975 raises the question, which we have reason to know is one of very frequent and considerable importance—namely, agreements between proprietor and manager as to the restriction of the latter from commencing business for himself within a certain area. The matter will arouse some discussion, and we shall be prepared to give a hearing to both sides.

The result of the recent sitting of the Berlin Conference on International Copyright has been semi-officially published in Germany, and, as predicted in our columns some weeks ago, special protection is to be granted to cinematographic works, whilst a better understanding with regard to photographic copyright should result in the case of the countries subscribing to the Berne Convention. (P. 959.)

The demonstration of methods and devices for the prevention of cinematograph fires was held on Thursday in last week at the Hippodrome, Leicester Square. (P. 967.)

Mr. Albert Smith's demonstration last week, at the Royal Society of Arts, of cinematography in natural colours showed the remarkable progress which has been made. It is anticipated that before very long animated photographs in natural colours will be available for public entertainment. (P. 960.)

Enlarging apparatus, a self-portrait lens cap, and an arrangement for obtaining negatives with stereoscopic relief figure among "Patent News." (P. 968.) We refer to the latter on page 958.

The second portion of the paper by Mr. Herbert E. Ives, describing his recent researches in the Lippmann process of colour photography, is given on page 955.

A point of interest to photo-micrographers is a recommendation made by Mr. J. I. Pigg as to the use of aniline dyes in preserving animal tissues. (P. 962.)

### EX CATHEDRA.

#### The Annual Index to the "B.J."

We shall present with the last issue of the present year, namely, December 25, the index to "The British Journal of Photography" for 1908. As in the case of indexes to recent volumes, it will be our endeavour to give a subject index which forms an easily comprehensible guide to the contents of the volume, yet does not run to an excessive length. We would ask our readers to note that we do not issue the index separately. It is presented with every copy of the "Journal" for December 25, and therefore those desirous of securing it are advised to make sure of obtaining this issue, which will be published immediately before the Christmas holidays.

#### Photographic Copyright in France.

As we have on several occasions pointed out, the French copyright law relating to photographs appears to be based on decisions in the Courts to the effect that only photographs of artistic merit are entitled to protection. The judges decide whether a photograph is a work of art or not, and their decision can be taken to the highest Court of Appeal. Hence it is interesting to read in the current number of "Le Procédé" an extract from the "Gazette des Tribunaux" of a judgment of the Court of Appeal which once more confirms this species of legislation in regard to photographic copyright. It is affirmed that "the photograph which is differentiated from an ordinary portrait by the pose of the subject, the arrangement of the accessories, and the whole manner in which the photographer has sought to reproduce the features of his model constitutes an original work, and may be classed with works of art entitled to protection under the ante-photographic French copyright Act of 1793." It is also affirmed that "the photographer who creates such a work (or his representatives) has the sole right to prepare copies for sale (excepting as the model may protest against the reproductions), and this, irrespective of the conditions as to payment—that is, whether the prints made for the subject were supplied gratis, at the ordinary price, or at a reduced price. In reference to the case of a photo-engraver, F, who may have reproduced such a photographic portrait without the consent of the proprietor of the negative, assuming that F establishes the fact that the photographic print from which the plate has been made was supplied to him by Madame B, who at the same time ordered 600 copies for frontispieces in her biography, a charge of infringement against F would be none the less valid, but F does not bring any vestige of proof, and he cannot justify the authorisation which he claims to hold from Madame B." It would almost seem from the above judgment, which appears to be

quoted verbatim from the report of the judge's summing-up, that under no circumstances is copyright the property of the person paying for the portrait, but it would surprise us to learn that this referred to the circumstances in which a portrait is taken in the ordinary way of business. We imagine it to refer only to the case in which a seller or model is specially invited by the photographer to sit.

### "Snap-shooting" and "Snap-shooting."

In a letter appearing in several daily papers Mr. Snowden Ward appears in the—to him—congenial rôle of champion of philological forlorn hopes. On this occasion it is "snap-shot" as an active verb which comes under his ban, on account of the ugliness of its derivatives—"snap-shooter," "snap-shooting," and "snap-shotted." Yet there are surely few who, on grounds of euphony, will resign these current words in favour of the suggested "snap-shoot" and "snap-shooting." While languages continue to be moulded by the people, and not by the purists and the pedants, we fear it is as futile to attempt the stifling of such words as it is to amend a word like "inflammable," or others philologically indefensible. And, after all, whether "snapshoot" or "snapshot," the crux of the matter is touched by another correspondent, who would have the "snap-shot" defined as "a hurried exposure made at short notice without time to adjust either speed of shutter or diaphragm of lens to speed of plate, light, or subject," and thus to be distinguished from, say, "hand-camera exposure," which term should be reserved for the properly conducted operation. Lexicographers, like Sir J. A. H. Murray, will perhaps make a note of this alleged distinction, in regard to which our contemporary, the "Globe," wittily remarks: "It is not so much the word that most people object to as the thing itself."

\* \* \*

### "Bromoil Demonstrations."

In the "Morning Post" Mr. Hector Maclean describes a recent demonstration of the Bromoil process before the members of the Cripplegate Society as the first demonstration of its manipulation, "at all events before any of the London photographic societies." We do not know how often the process has been dealt with under the title of "oil printing," but under its own name it has certainly been demonstrated at least four times in London—before the R.P.S., the South Suburban, the South London, and the North Middlesex Societies. In the provinces our pages only record three demonstrations, exclusive of the second Birmingham demonstration of December 8, but we have no doubt that numerous others have been given. It would, indeed, be strange, as Mr. Maclean suggests, if a process became so firmly established in one year without the aid of society demonstrations, but it seems to us even stranger that the R.P.S. and three of the most important London societies should have been able to put the subject in their programmes without Mr. Maclean's cognisance.

### The Scottish Salon.

Details are not yet complete, but we understand the entries received exceed a thousand, and all the leading workers are represented; while not a few Scottish workers south of the Tweed, and in Ireland, have promised to send work to meet the scrutiny of the Board of Selection. The Salon Committee have left no stone unturned to interest local people in the approaching function, and last week one of the local papers appeared with a portrait of and interview with the Salon secretary, while the other paper in the burgh, not to be behind, came out with a portrait and interview with the

Federation secretary. The result of this judicious booming is that the Salon is already the one subject of conversation in Wishaw, and the representatives of the Press vie with one another in emphasising the importance of the visit of this national exhibition. Much is heard now of the oppressive results of the railway combine, but the Salon secretary has evidently got behind that, and a special train will be run from Wishaw to Glasgow, leaving at 10 p.m. and stopping at every station; this should result in a big attendance of Glasgow folks. The programme of entertainments is very complete and varied, and everything points to a successful Salon week. The work of the late Horsley Hinton will represent England—a graceful compliment, and what might be called an "In Memoriam" of his visit to this exhibition at Aberdeen last season. Dr. E. G. Boon, Alassio, Italy, is the other "foreigner," and he is sending a special one-man show, much of it being new work which is coming direct from Italy. An unusual compliment is paid to Reid o' Wishaw, the doyen of photographers of animals and birds, in the exhibition of a one-man show of his work, but in this case a prophet hath honour in his own country.

### Some "Stereoscopic" Patents.

Some time ago we referred in these notes to Dr. Alfred Smees's system of binocular perspective, and to the way in which he applied it in photography by using a camera kept in continual lateral motion throughout exposure. Another method of producing very similar results now forms the subject of two different patents. In each patent two separate lens systems are used, and the final result is the superposition on the plate of two stereoscopically dissimilar images. So far as we can see from the descriptions, exactly similar results could be produced by superimposing the images forming the two halves of an ordinary stereoscopic negative. In other words, an "anaglyph" print, in monochrome instead of colour, should give all the effects of relief and solidity that the patentees claim are produced as the result of using their wonderful inventions. Each inventor very definitely claims that the results show relief when examined by ordinary binocular vision, but neither seems to have any idea of the absolute futility of the invention. In a picture made by Smees's method the relief is only apparent when both eyes are fixed on a particular point, the point of sight, and if a similar effect is to be obtained by superimposing a stereoscopic pair the most accurate registration of the two points of sight will be necessary. At the best the result obtainable is not worth anything, the so-called "relief" effect being very feeble and of such an elusive and momentary character that the great majority of observers will never be able to see it at all. In fact it cannot be seen unless one knows the scientific principles that govern the effect, and also understands the proper way of looking at the picture.

### The Deterioration of Negatives.

A week or two ago we published a letter by "Observer" challenging our remarks in favour of varnishing negatives, and suggesting that unvarnished negatives fare best when splashes or condensation drops exist on the films. He sent us a specimen of a varnished negative that presented a very curious and interesting crystalline appearance, something like that produced by acids on polished tin. The pattern was impressed in the gelatine as well as in the varnish, and its cause was somewhat obscure. It may have been due to the crackling, in a damp atmosphere, of an imperfectly waterproof shellac varnish, while, on the other hand, it may have been caused by the crystallising of some saline solution. It is, however, not the only effect.

Our correspondent is, perhaps, unaware that the negative film contains large and healthy moulds that have found their way into the gelatine at some time or other. If these got in after varnishing then the varnish must have been very ineffective. If before varnishing them, the destruction of the varnish may have been due, at least in part, to the growth of moulds underneath. Evidently this negative never had a fair chance of proving its ability to resist damp.

### THE INTERNATIONAL CONFERENCE ON COPYRIGHT.

THE results of the Berlin Conference on the Articles of the Berne Convention have been semi-officially published in Germany. These confirm the forecast which was published in "The British Journal of Photography" immediately the Convention had finished its sittings, enabling those interested in them to examine more closely the various changes in the Articles. As was remarked at the time, these changes are not numerous, and none of them of sufficient importance to cause any sensation; yet what changes there are, are for the better, showing a decided advance, and, what is more comforting to the photographer, the determination to accord him more than ever his just rights in the control and profits accruing from his works. Let us give briefly the contents of the various Articles, in so far as they affect photographers and photographers.

Article 2 states clearly that protection is given to all "works of science, literature, and art." The word "art" embraces all productions or creations, no matter what mechanical process or means may be employed in the manufacturing and multiplying of the same. Under this head are mentioned drawings, paintings, engravings, lithographs, illustrations, sketches, and photographs. All copies produced from the original work enjoy the same right of protection as the original work itself, and it is distinctly forbidden to copy these, to adapt them in any way that may be calculated to interfere with the original copyright, or by arrangement or altering, such as composing, to tamper with any copyrighted work. All countries within the Union are bound over to respect these rights as far as the laws in force in the different countries permit of such protection.

The new reading of Article 4 is: The enjoyment and exercise of these rights is not associated with or bound by the necessity of complying with any forms whatever.

By this it would appear that a decided advance has been made upon the generosity of the new copyright law which came into force in Germany at the beginning of the present year, and was fully reported in the "B.J." at the time (see issue for April 10, 1908). In the German conditions it will be remembered that the only thing necessary to make a photograph copyright was to print on the photograph the name and address of the producer and the date of its production. Even this precaution will be no longer necessary when the new law comes into force in 1910. This is indeed good news for photographers, who from the above-mentioned date will have the absolute right and control of their own productions. It must, however, be distinctly understood that by their own productions is not meant or inferred such photographs as are taken by them on commission, or for which they are paid by any other party for taking. In such cases the copyright belongs to the party or parties giving such order or commission, or who pay the photographer for taking the original photograph, and they may forbid the photographer from duplicating it, exhibiting it, or in any other way using it or causing it to be used contrary to

their desires and wishes. Consequently, the numerous businesses which trade mostly in the copying of ordinary portraits—that is, portraits or other photographs taken to the order of the parties having them copied—will in no way be affected by the new law. Yet in their own interests it would be strongly advisable for them to have a guarantee in writing, and signed by the person ordering the copies to be made, to the effect that he had ordered and paid for the original photograph, and that therefore the copyright is his own property. This precaution would at least exonerate the photographer of all blame should complications afterwards arise and the right to make the copies be disputed.

As was recorded in our previous article on this subject, the branch of photography that received special attention at the Berlin Conference was in its application to the cinematograph. This is easily accounted for, since cinematography was practically unknown at the time of the Berne Convention, and was in such a primitive state of its development at the time of the last Paris Conference that the time was not then considered ripe to deal with it specially. Since there is no condition in any of the earlier articles regarding it, there has always been until now some doubt regarding its actual legal position in the reading of the copyright law. For instance, the cinematographer has had no scruples to take for his subjects scenes from popular novels, fashionable plays, and such-like; most likely without ever so much as suspecting that he was infringing the copyright of such novels or dramas. With these difficulties the Berlin Conference has dealt very fully. It has shown its appreciation of the enormous advance that the cinematograph has made during the last few years, and has devoted a whole Article to the subject. According to this Article, No. 14, it will in future be illegal to reproduce by the cinematograph scenes or actions from copyright works without the express permission of the holder of the copyright. The wording of the Article is: The holder of the copyright of any literary, scientific, or artistic work has the sole right of permitting the reproduction of such work or works by means of the cinematograph and its production in public. The same protection which is accorded to works of literature, science, and art applies also to original and independent cinematograph productions of all kinds, provided that the author of such productions has given to them, by the arrangement of his subject, or in some other way, the characteristics of an original personal work. This is perhaps a little vague, and is open to considerable doubt as to what is really meant. Therefore it is to be hoped that before the official text finally appears in English the wording of it will be at least more intelligible. Cinematograph productions from subjects in literature, science, or art, which subjects may be already copyrighted, but which productions are made by the permission of the original copyright holder, enjoy the same protection as original works. All the above conditions apply equally to all works produced by any other means similar to cinematography.

The inclusion of cinematography under the "Artistic Copyright Law" is assuredly the most natural and reasonable way out of the numerous difficulties and court cases to which we have frequently drawn attention in our columns, and settles finally those legal points out of which these difficulties have arisen. (See "B.J.," May 8, 1908, p. 355; also December 15, 1905, p. 998.) As hinted above, the reading of the phrase, "characteristics of an original personal work," is not as clear as it might have been, and is suggestive of loopholes and legal quibblings. This seems to leave it entirely for the judge in any case which may arise to define what constitutes "an original personal work."

## CINEMATOGRAPHY IN NATURAL COLOURS AT THE ROYAL SOCIETY OF ARTS.

THE large lecture theatre of the Royal Society of Arts in the Adelphi was crowded to the walls on Wednesday in last week, December 9, when Mr. G. Albert Smith lectured upon and demonstrated the process of two-colour cinematograph projection, which has been worked out by him, and has been alluded to in past issues of this journal. Since last December, when we wrote ("B.J." "Colour Photography" Supplement, December 6, 1907) as the result of a visit to Mr. Smith's laboratory, the process has passed from the experimental to the commercial stage, and those who, like ourselves, have seen the first results obtained by the inventor will agree that we were warranted in predicting, a year ago, the perfection of the process to a degree at which it becomes of every-day service for instruction and entertainment.

We have just described Mr. Smith's process as "two-colour," but it must be borne in mind that the phrase applies only to the method adopted—namely, the use of two taking and two projection filters; in other words, to the making of the colour record positives in pairs instead of in sets of three, as in the customary three-colour process. As the audience at the Royal Society of Arts saw for themselves, the two-colour method proved itself capable of giving a range of colours equal to that of a three-colour process, as was seen from a comparison of Autochrome records of posed subjects and the cinematograph version of the same figures in motion. And the best of the pictures shown on the screen, particularly some of a harvesting scene, of a yacht race, and of a girl playing with pet rabbits, showed the fine rendering of colours, and especially of neutral greys, etc., which the two filters of Mr. Smith gave. Not only this. A series of three-filter is found by Mr. Smith to make too great demands on human persistence of vision, when, as in the Smith system, the separate positive colour-records are projected in rapid succession on the screen and combined in the eye of the observer. This system, the lecturer pointed out, was the one which had been found practicable after a trial of methods involving registration of three pictures. The conclusion to be drawn from the part of Mr. Smith's paper, which we reprint below, dealing with the alternative methods in natural-colour cinematography, is that a two-record process appears to be the only practicable solution of the problem, and such certainly appears to be the case, excepting that a "screen-plate" colour film, if obtainable of sufficient rapidity, would equally well respond to the commercial conditions under which natural-colour cinematography has to be done. With these comments upon the most convincing and beautiful demonstration of the success obtained by Mr. Albert Smith, we will quote, with some abridgement, the more technical portion of the paper, the full text of which is published in the "Journal of the Royal Society of Arts" for December 11, 1903:—

The three-colour principle having been proved by numerous lines of demonstration to be a sound working theory, it would naturally suggest itself as being applicable to animated pictures; and, judging by the records of the Patent Office, there are plenty of people who have thought so. But it is to be feared that in the rush to the Patent Office the details of experiment and trial have generally been overlooked.

Some years back (1902), I was invited by Mr. Charles Urban to assist in a thorough trial which he was making, regardless of reasonable expense, of a three-colour process applied to the cinematograph. At that date very little was known about the possibilities of sensitising film to red and green, and, to that extent, we were handicapped, although we had very expert assistance. Nevertheless, in good sunlight we did succeed in taking a few negatives in which the three colours were duly recorded.

It was when we came to superimpose the pictures on the sheet through three coloured glasses that we found the process unworkable. As soon as the handle of the projecting machine was worked the three pictures refused to remain in register, and no knowledge that any of us could bring to bear upon the matter could even begin to cure the trouble. I do not know whether any other workers, if there are any, succeeded where we failed; but, if they did succeed, the public have never, so far as I am aware, been permitted to see the results. The difficulty is mainly due to the fact that cinematograph pictures are small to begin with (about the size of a postage stamp), and they have to be enormously magnified in exhibiting, as you all know. The slightest defect in registration is pitilessly magnified, and when the minute defects of registration in the first three pictures are followed by minute defects of another sort in the next three, and by yet another sort in the succeeding three, and so on throughout the length of a film, the effect on the observer is almost unbearable.

### Three-lens Systems.

A plan much recommended, and much patented, I believe, is to use three lenses in taking the negatives, with a colour filter behind each, and to use a similar contrivance with three lenses and colour filters when projecting, adopting one of the usual contrivances to superimpose the images issuing from the three lenses. Whether the persons who advocate and patent this plan ever descend to the trivial detail of trying it is unknown, but when Mr. Urban and I tried it with carefully made machinery, the results were astonishing and painful to behold. It becomes evident on trial that the three pictures taken through the three lenses, however close the proximity of the latter may be, are slightly different from each other, and the attempt to superimpose these slightly different pictures when they are highly magnified, results in unbearable confusion.

### Three-colour Pictures.

The next idea we worked upon was to abandon the attempt at mechanical registration of the three pictures, and to run the films through the projecting machine at such a speed that the colours on the revolving shutter would combine, and so give the desired effect by persistence of vision. This was successful, but the colours were washy and ineffective. In fact, the colours were so pale that, considering the amount of film used up (three times the usual number of feet per subject), and considering that the problem of exposure was made three times as difficult, the experiment assumed a less hopeful aspect. The death of the original patentee put a further damper on the inquiry, and the experiment finally dropped.

### The Commercial Condition.

During the last four years, with the support of Mr. Charles Urban, I have renewed the inquiry, to the exclusion of almost all other work. I have concentrated attention specially upon four points:—1. Sensitising the film to all colour waves, specially pressing the sensitiveness as far into the red end of the spectrum as possible. 2. Superimposing the colour records by persistence of vision. 3. Compressing the colour records into a less number than three, so as to give the least possible interval of time between successive presentations. 4. To conform to the condition that any scheme must be easily applicable to the existing cinematograph machinery, and that the standard film with standard perforations must be used, so that any successful results might be readily adopted by every cinematograph user without much trouble or expense.

The first of these lines of inquiry (sensitising) has been already referred to; it simply consisted of repeated trials and experi-

ments day by day for a year or more until the required conditions for sensitising emulsions for cinematograph work were better understood. The third line of inquiry, that of reducing the number of pictures in which the colour waves could be recorded in a monochromatic scale from three records to two, also resolved itself into a matter of repeated trial. For, in addition to deciding upon the particular shades of grey deposit which should be adopted as the equivalent of particular colours, the variations of different emulsions in yielding these greys had to be taken into account. The final deduction from the experiments under the third heading was that, proceeding from the red end of the spectrum, all rays from dark red to blue could be recorded in proportions which our eyes accept as sufficiently truthful through two filters only.

If we ask individuals to set down the principal colours of nature, placing them in order of luminosity or brightness to the eye, the average of the lists will be as follows:—White, yellow, orange, red, green, blue, violet, indigo, black.

Now, reference has previously been made to the unfortunate fact, that photographic plates or emulsions do not see as we do; thus, to the plate, blue and violet come at the top of the scale next to white, and not at the bottom end, as they do in the luminosity scale. I find that it is possible with two carefully adjusted filters to pass to the sensitised plate or film colours in proportions parallel to the above order. Through one filter I pass white and yellow, then on through orange and scarlet to the darkest red I can sensitise for. Through the other filter I pass white and yellow again, as these two are at the head in luminosity and require fullest representation; then on through green, blue-green, blue and violet in the proportions suggested by the above luminosity list. The aim is to secure, by a careful adaptation of filters to emulsion, a record of colour luminosity stated in gradations of tone from white to black through a scale of greys, this scale being fully represented in two successive pictures.

I take the pictures with an Urban bioscope camera fitted with the required filters to come into action alternately. One film only is used, of the usual standard size, and I take the pictures at the rate of not less than 16 per second through each filter, or 32 pictures per second in all.

When the negative record has been duly developed, and a positive transparency made from it, this positive transparency represents, by its gradations of tone from white to black in each successive pair of pictures, not only a record in form and shape, but it also acts as a filter or sifter of light; for when it is passed in the path of rays of coloured light it will screen or filter them so as to reconstruct for our eyes the various proportions of colour luminosity which were present in the scene when the record was made.

#### Taking and Projecting Filters.

I have said that the photographic record now obtained is to be placed in the path of colour rays, which rays are to be sifted by the travelling record so that the required amounts of colour reach the projection sheet in due proportion. The question now is, What rays of colour are we to use? Apparently, we must use the same colours that we used as filters in the camera, and, in fact, we may do so with pleasing results. But theoretical critics will point out that, owing to the unfortunate over-sensitiveness of the film to violet and blue, we must, of necessity, have cut these colours down to such an extent in our camera that if we use the same filters for reconstructing colour for the human eye, their absence will be sorely missed—our whites will be so deficient in blue and violet, that they will not be white at all, but orange or yellow.

One reply to this contention is, that white is very largely a comparative sensation. What we agree to call white in a painting, for instance, is often quite different from what we agree to call white in another painting if we take steps to compare the two "whites" with one another. One may be yellowish or

greyish compared with the other, yet both are white enough in their proper place in the picture, when surrounded with colours in proper "key," as it were, to them. Again, the whitest of paper will look yellow when compared with the purer white of fresh fallen snow. Therefore, our whites produced by the mixture of coloured lights may possibly be somewhat yellow as a matter of spectroscopic reality, but if the human eye accepts them as white by comparison with other colours in the same picture, we need scarcely bother our heads further.

But another way of meeting the critical objection that the analytical filters of our camera are necessarily too deficient in violet and blue to give a proper rendering of colour when used as synthetical or reproduction filters in projection is to introduce the missing beams of violet and blue into our projection instrument, and so make ourselves practically secure of the white, or "all-colour light," required on theoretical grounds. This I find it an advantage to do; and if you examine the light emanating from the projecting machine when lighted up and at work, you will see that beams of red and green are alternately issuing from the lens, and that these beams have added to them by means of a supplementary shutter just those proportions of violet and blue required to make a pure white when all are mixed. Thus we have light on the sheet for our whitest objects which contains, as it should contain to conform to theory, every colour of the spectrum from dark red to violet.

There are some persons so obsessed with the idea that three is the magic number for filters, that they imagine a system in which two only are employed must necessarily restrict the colours recorded and produced to two. There is, in fact, a good deal of confusion on the subject of colour mixture, and there are not a few who argue as though mixing coloured lights and mixing coloured pigments were the same thing. No mixing together of two or more pigments will ever make white; but the white light can be produced by the mixture of two correctly chosen coloured lights. The printer who has to make colour prints on paper certainly has to divide the spectrum into three, or even four, but he is dealing with printer's ink or paint, not with light at all. Every writer on the phenomena of light, including Tyndall and Sir Henry Trueman Wood, teaches that white light can be made by the proper mixing of two well-chosen coloured lights; and it is further taught by every authority that white light contains all colours. I hope, however, to demonstrate that by dividing the spectrum into two it is possible to exhibit satisfactorily every colour to the eye, including the purest white.

The practical method sketched above is possibly open to assault on strictly theoretical grounds—although it must not be forgotten that theories have sometimes to be re-examined in the light of facts. The first consideration, to my mind, is the production of results. I am not striving to defend a theory; nor do I deem it necessary to keep within the limits of a theory.

I have no doubt whatever that many improvements are in store. Lens makers, emulsion makers, mechanics, will each contribute to the advance. I expect to make important improvements myself when spring comes and I renew my experiments. The present results are presented as early experiments in the photography of moving things in colour, and as the first serious exposition of work done in that direction. It is to be hoped that the numerous others who, we are led to believe, are working in the same direction will be encouraged to put their theories to the test and come forward with their results.

G. ALBERT SMITH.

ROYAL PHOTOGRAPHIC SOCIETY.—As we go to press some information reaches us in the shape of a document relating to the internal affairs of the Royal Photographic Society. We would like to have found space for its insertion in the present issue, but are compelled to hold it over until next week, when it will come before Fellows and members of the society in time for them to give it their consideration during the Christmas holidays.

## ANILINE DYES AS A PRESERVATIVE FOR ANIMAL TISSUE.

WHEN a series of photographs of a dissection of fresh animal tissue has to be made, great difficulty is often experienced in securing the necessary photographs before decomposition has commenced.

In many cases the specimens can be placed in a preservative solution, such as formalin or bichromate of potash, but these preservatives have a hardening effect on the tissues, which renders subsequent dissection much more difficult. Practically, all the preservative agents in general use have a tendency to harden animal or vegetable tissues.

When the specimens are intended for section cutting in microscopic examination, this hardening effect is a great advantage; but, in dissecting, the hardened tissues are often extremely difficult to separate.

On account of the trouble involved in disintegrating preserved tissues, the advice is frequently given in text books that fresh specimens should be used for dissecting delicate structures.

This advice is easily followed when the operations can all be completed within the course of a day or so, but when the work is prolonged for several days, some method of preserving the material must be adopted.

When a series of photographs are required of the dissection, considerable time has to be spent in obtaining satisfactory negatives, especially when a magnification of eight or ten diameters is required, as the negatives have to be taken by reflected light.

When fresh specimens are easily obtainable, there is, as a rule, no great difficulty experienced, as a fresh dissection can be made when necessary; but when rare objects are being studied,

it is practically impossible to finish a prolonged course of scalpel and camera work before the specimen is spoilt by the combined effort of bacteria and paramacia.

By accident, the writer found that animal and vegetable tissues stained in aniline dyes will undergo little alteration for a week or more. A partially dissected Rana Larva had been stained for photographic purposes, and was left in tap water for several days.

These animals, owing to the nature of their habitat and diet, rapidly decompose after death, but this stained specimen had remained unaltered, and no animalculæ were visible. The tissues were apparently in the same condition as when they were first placed in the water, and dissection was carried on as easily as with a fresh specimen.

The presence of the dye does not render the subsequent dissection more difficult; if anything, it is easier, as the staining generally brings out the various organs more clearly. A further experiment was made with a goat moth caterpillar, which, being a somewhat rare grub, would, in the ordinary way, have been preserved in Müller's fluid. This remained in perfect condition for two weeks, by which time the necessary photograph had been taken.

Experiments have shown that a fairly strong solution of analine dye is immediately fatal to the flagellata and paramacia, which are the most energetic agents of decomposition; the dye preserves the tissues by obviating the existence of these protozoa, and does not affect the substance itself.

J. I. PIGG.

## STUDIO SCENES.

### UPPER GRADE.

*The interior of a reception room in a West-end photographic establishment. A young lady discovered occupied in her duties. The swing doors are opened by a man in livery. Enter a lady, corpulent and past her prime. The young lady "receptionist" steps forward and "receives" her after the manner of her kind. This done to the satisfaction of both, she opens the door of a cabinet and turns over a few mounted photographs of ladies somewhat of the condition and estate of the visitor.*

LADY VISITOR: "Oh! these are quite charming; but they are all elderly ladies, aren't they? May I see?" (She rolls her chair towards the cabinet and begins to turn over the specimens.) "Now, this is better" (holding up a likeness of a young slim and very beautiful girl). "Now, that's how I should like to be taken. I think that's perfectly lovely. Don't you think so?"

RECEPTIONIST: "Yes, she's very lovely. She's the Hon. Miss (mentioning the name of a debutante famous for her youth and beauty). "Of course, we could take you like that, in that position, and with the same background; but don't you think this would be perhaps a better guide?" (Takes up a photograph of a lady of about 35, handsome and of fine proportions.)

LADY VISITOR (drawing in polite consideration): "Y-es; but isn't it just a little old?" (Reverts to the first example). "This, you know, takes my fancy. Please make me like that. I'm sure my husband will be so charmed if I come out like that."

RECEPTIONIST: "We'll do our best, madam, of course. When would you like to come?" (They arrange an appointment. The Lady Visitor then turns to examine the photographs that decorate the reception room.)

LADY VISITOR: "I can't think why you do these with the black faces" (pointing to a head in a broad deep tone with a light background).

RECEPTIONIST (much astonished): "Black? Oh, that isn't black, it's simply taken in a slight shade with a light background. It's very much admired by some people."

LADY VISITOR: "That may be; but it's black, now, isn't it? And people's faces are not black, they're bright. I think the background ought to be dark and the face ought to stand out nice and bright. That's how one would expect a photograph to come out, isn't it?" (She singles out other errors in art with her lorgnette as she makes a tour of the room, delivering enlightening dissertations upon each. The Receptionist humours her in monosyllables. Upon reaching the folding doors the man in livery opens them. Exit the Lady Visitor with a smiling motherly nod to Receptionist.)

RECEPTIONIST: "Vain old pig!"

In a few moments a gentleman is shown in. He is tall and rather awkwardly big. The Receptionist, who expects him, conducts him into an inner chamber, where he finds all the paraphernalia of photography. Greetings pass between him and the operator.

GENTLEMAN VISITOR: "Now, you know, my idea is that all this posing and arranging is a gigantic mistake. What? People don't look like that in real life. Now, I want to look natural. I don't care to have it done at all if I'm to be stuck up with a book and all that sort of thing. You know what I mean. What?"

OPERATOR: "I think we shall be able to manage without anything undesirably conventional. Suppose we try this chair" (Wheels an easy chair in front of the camera.)

GENTLEMAN VISITOR: "Now, this is my idea." (*He drops into the chair, crosses his legs and remains full face to the camera.*) Now, that's characteristic! That's natural! Won't that do?"

OPERATOR: "Well, I'm rather afraid that if I took you like that you would be justified in demanding another sitting."

GENTLEMAN VISITOR: "Why?"

OPERATOR: "Because your face would not seem to get the importance due to it in the pictorial scheme, whereas your boot-sole would have the lion's share of interest."

GENTLEMAN VISITOR: "Ah! I suppose that is so. I confess I never thought of that. Well, I'll put my feet on the floor. There!" (*He now adopts the pose of an Egyptian statue in the British Museum.*)

OPERATOR: "If you don't mind I think we might dispense with the chair altogether. Except for little people, chairs are rather a nuisance. May I try a standing pose?"

GENTLEMAN VISITOR: "Well, if you like; only, how long is it going to take?"

OPERATOR: "Oh! about a quarter of a second." (*The Gentleman Visitor squares up to the camera, his legs rather straddled and his hands in his trousers pockets.*) "I think a three-quarter view would be really fine. Would you mind just going as though you were walking away and then just look back a little?"

GENTLEMAN VISITOR: "Hang it, man, I never look back, and I don't look at people in three-quarters, as you call it! I like to look people straight in the face. What's the objection to taking me as I am?"

OPERATOR: "None whatever, only I fancy you will think it a little stiff when you see the proof."

GENTLEMAN VISITOR: "Well, what if it is? What?"

OPERATOR: "Very well, I'll make an exposure as you are, if you'll allow me to take one as I should like it."

GENTLEMAN VISITOR: "That's fair enough. Go ahead, then." (*Operator goes ahead.*)

GENTLEMAN VISITOR: "Is it done? Good! My word, how quickly you fellows earn your money!"

(*He patiently submits while the operator makes three or four exposures more upon his client's most becoming phases*)

GENTLEMAN VISITOR: "I suppose you know you've got four to my one. However, I know the one of the lot that will please me"

OPERATOR (*smilingly*): "Don't let us discuss that until we see the proofs."

Gentleman Visitor shortly takes his departure, saying, as he goes out: "Well, you mustn't be surprised if I throw all yours back on your hands and select my own. Good day."

CURTAIN.

#### LOWER GRADE.

*Scene the First: A shop window in the neighbourhood of Bermondsey. Upon the fascia is emblazoned the legend "Electric Studios." The usual easels bearing oil-painted enlargements, and a spotty display of prints, adorn the window. A large ticket announces that three cabinet photographs may be had for the sum of two shillings. A young man attired in the height of lower middle-class fashion gazes at the placard deep in thought. He wears a double collar and a striped necktie fastened with a gilt safety-pin. His brown boots are of a tint leaning towards a chrome yellow.*

YOUNG MAN: "By Jove, that's not dear. She'd be better pleased with three of them than with the midgets. Bless if I don't go in and have 'em done." (*He looks into a narrow advertisement mirror upon the jamb of the adjoining shop to assure himself that his appearance is all that could be wished; adjusts his handkerchief so that a small white triangle peeps out of his breast pocket, and then, with a little cough, enters.*)

*Scene the Second: Interior of the same. A curtain obscures the back portion of the premises. The young man enters to the*

*clanging of a bell attached to the top of the door. At this signal the curtains are divided, and the Proprietor appears.*

PROPRIETOR: "Good afternoon, sir."

YOUNG MAN: "Good afternoon. Er—I see you do three cabinets for two shillings."

PROPRIETOR: "Quite right, sir. Can I have the pleasure of doing three for you? Or we can do you a dozen for six shillings."

YOUNG MAN: "I think three'll be enough, thanks."

PROPRIETOR: "Very good, sir. Will you kindly step this way, sir?" (*He holds back the curtain so that the young man may pass through to the studio, a back shop with a skylight. The walls are distempered a grey colour. A property stile stands in one corner, a balustrade of the same description in another, and a canvas representing a cottage window, with a shelf attached in lieu of a window-sill, leans against a wall*)

YOUNG MAN (*with a little cough*): "I don't go in for these luxuries myself. Don't consider myself good-looking enough; but I'm just doing it now to oblige a friend."

PROPRIETOR: "Quite so, sir. Will you take your hat off? Perhaps you'd like a comb and brush. You'll find one behind that screen." (*The young man removes his hat and surveys his hair in a glass; finds it quite satisfactorily plastered down, readjusts his peeping pocket handkerchief and announces himself "fit." The Proprietor places him in a chair and directs his gaze to a point upon an adjacent wall, then ducks beneath the camera cloth. Having next retired into a cupboard and duly reappeared with a dark-slide, which is placed in position, he stands with the bulb in his hand, and gives the warning.*)

YOUNG MAN: "Hold on a minute. How'd it be if I had that button-hole? (*Pointing to a wired rose in a specimen glass that adorns a little three-legged table in faded black and gold.*)

PROPRIETOR (*always anxious to oblige*): "Certainly, sir."

*Hands the flower to the sitter, provides a pin, and assists at the decoration. The Young Man now expands his chest, elevates his chin, and tells himself that he will look "O. K. in the photos." The ceremony is then completed.*

YOUNG MAN (*in a louder voice to the Proprietor, who has again retired to the cupboard*): "Let's see, you send a proof or something, don't you?"

PROPRIETOR (*from the hidden depths of the cupboard*): "No, sir, I'm sorry we can't send a proof for three. If you care to take a dozen we'll send you one by post."

YOUNG MAN: "Dozen be blowed."

PROPRIETOR (*emerging*): "They'll be ready on Saturday, if you'll look in then."

YOUNG MAN: "Righto!" (*He proffers a "Woodbine," adieux are exchanged, and the Young Man exits very pleased with things generally.*)

*Scene the Third: The same, a week later. Enter the Young Man through the bell-clanging door, as before. Enter also the Proprietor from between the curtains, as before.*

PROPRIETOR: "Good afternoon, sir; I'm just finishing off your prints." (*Disappears.*)

YOUNG MAN: "Glad to hear it."

*Proprietor emerges with a mounted print, which he submits with a satisfied air, and watches his customer's face. The Young Man remains calm, but is evidently under the impression that he is more of an Adonis than the photograph represents him to be.*

YOUNG MAN: "H'mm. Well, I can't exactly say I'm pleased with it."

PROPRIETOR: "Indeed, sir! What's the matter with it?"

YOUNG MAN: "Well, I don't believe I look like that. Did I stick my face up like that? If I did you ought to have told me of it. I look a silly fool. Besides, look at my moustache! It don't stick out away from my face like that, does it?"

PROPRIETOR: "O yes, that's all right, sir. You see you aren't used to seeing yourself at that angle. You only know yourself full-face, like you see yourself in the glass."

YOUNG MAN (*after an awkward pause*): "Well! You'll excuse me, but I think it's rotten."

PROPRIETOR: "I'm sorry you think that, sir. Myself, I think it's very good. Just wait till you've shown it to your friends before you make up your mind that it's not good, and then if you're not satisfied I'll do you three more at half-price."

YOUNG MAN (*mollified*): "All right! Let's have 'em. I've got to catch a train."

PROPRIETOR: "I shan't be a moment just touching up the others." (*He disappears.*)

YOUNG MAN (*raising his voice*): "They don't want any touching up. You can't do 'em any good if you touch 'em up for a week."

PROPRIETOR (*within*): "I can't let any prints go out untouched."

YOUNG MAN: "What's it matter? Nobody 'll see 'em. I'm going to tear 'em up."

PROPRIETOR: "You can do what you like. It's against our rules to let anything go out that's not been retouched."

YOUNG MAN: "What rot! What's the good of keeping me waiting here while you're tinkering with 'em? Don't I tell you

I've got to be off to catch a train? You can't do 'em any good. They're wasters."

PROPRIETOR (*returning with the three prints, which he places in a neat envelope, and hands to the Young Man*): "You'll find they'll give satisfaction sir, you take my word for it."

Young Man throws down a florin and exits without adieu and without offering a "Woodbine," but muttering: "Fool and his money soon parted."

Scene the Fourth: Front parlour of Miss Lovelite at Balham. Miss Lovelite and the Young Man discovered sitting on a hard and shiny sofa bedecked with crochet antimacassars.

MISS LOVELITE: "Well, let's have a look at 'em, anyhow. P'raps I shall like 'em."

YOUNG MAN (*producing the envelope*): "I don't think!"

MISS LOVELITE (*gazing, a smile rapidly overspreading her features*): "My boy, you never looked half as nice as that in all your natural. They flatter you. That's all the matter with them. I must go and show 'em to Ma." (*Exit, leaving Young Man a prey to mixed emotions.*) [CURTAIN.] F. C. T.

## THE KAISER AND PHOTOGRAPHY.

JUST now, while there is so much talk about the Kaiser's political opinions, it may be interesting to photographers to know his opinions regarding their profession. It is a well-known fact that he is one of the most frequently photographed crowned heads in Europe. It is estimated that he is photographed at least two or three times every week, and if one may judge by the popularity of the numerous postcards of him which are on sale throughout the whole Empire, this statement would seem to be more than verified. One sees him in an endless variety of poses and guises. In one he is seen quietly walking, accompanied by the Kaiserin, or other member of the Royal family, in the Tier Garten, Berlin; in another, we see him mounted on his war horse directing a miniature battle; in another, he is on the bridge of a battleship giving orders to the crew; or it may be that we see him careering after the hounds at a fox-hunt. His public and private, naval and military life is all fully recorded in all its details by the camera, and the pictures are so familiar to us that one cannot pick up a newspaper or magazine without seeing the representation of some new phase. Unlike King Edward, the Kaiser has no objection to the snapshotter. On the contrary, the latter is encouraged so much that he is usually in attendance wherever the Kaiser is. King Edward's dislike to the camera has become proverbial. On one occasion the present writer had some experience of this. He was present at a Royal function, and, after going through the customary formalities in order to obtain permission to use his camera, was rewarded by a reproving glance from Majesty, who was evidently startled by the click of the shutter. With this tell-tale click the Kaiser has become so accustomed that he pays little heed to it. He is even accustomed to the less familiar whirr of the cinematograph, and his great interest in this is shown by the fact that he often whiles away evenings in his family circle or entertains his guests with a presentation of moving pictures of his various travels. Recognising its educational value, he has presented various sets of cinematograph apparatus to scientific institutes, and recently a public school was the recipient of this distinction.

Coming to more legitimate photography—that is to say, those occasions on which the Kaiser poses intentionally in front of the camera, he is noted as an ideal sitter who, while he has his own ideas, gives the operator little or no difficulty.

Naturally, a command to photograph his Majesty is considered the highest honour that can fall to the lot of a photographer, and is the cause of no little bustle and excitement; yet the Royal sitter is so accustomed to posing to painters and photographers that he knows instinctively what is expected of him. The only thing is that he is somewhat impatient; the operation must be performed as quickly as possible, therefore the room must be arranged beforehand, the camera focussed, and everything in readiness when his Majesty comes. Few words are exchanged during the interview, for the Kaiser has usually studied the subject before coming to face the camera, and assumes such pose as he considers in keeping with the costume he wears, or character he represents. He is not, however, above taking a hint, or even soliciting the operator's opinion, and readily falls in with any suggestions offered by the latter. When he has time and is in the humour, he will even stop to ask a few questions regarding the recent progress of photography, and on such occasions the informant must be in a position to give precise and ready answers, for the Kaiser is no novice in the art, having on various occasions given proof of a knowledge of the subject. These calls on the various Court photographers to photograph his Majesty are not nearly so frequent as are the activities of the ubiquitous snapshotter. Yet when we say that the Kaiser has in his wardrobe something like over two hundred different uniforms of the various home and foreign regiments and navies of which he is the chief or honorary chief, to which he is every now and then adding a new one, in all of which he is photographed from time to time, the reader may be able to form some idea of the frequency of the visits of the photographer to the Palace. Added to these are the various sporting and private portraits which are taken at frequent intervals. On very rare occasions has the Kaiser visited the studio of the photographer. Usually the Royal commands are executed in one or other of the various palaces, in which a room is set apart for the occasion, and the operator has to make shift as best he can with the lighting and other necessary arrangements.

There are in albums in the palace libraries photographs which the Kaiser has himself taken with the camera during his younger days. But of late he has seldom or never done any practical work in photography. This is not so much through lack of interest as through lack of time to prosecute

it thoroughly. For the most part he prefers to leave photography to the Kaiserin, who, like Queen Alexandra, is an adept with the hand-camera, and some years ago permitted to be published a series of photographs of the Royal children engaged in their various games and pastimes: a collection which did

her much credit. The Princes and the young Princess are all of them enthusiastic photographers, and when they accompany their Royal father at home or abroad are nearly always to be seen with a hand-camera slung over their shoulders.

## AN EXPERIMENTAL STUDY OF THE LIPPMANN COLOUR PHOTOGRAPH.

### II.

It appears, therefore, that the standing waves are actually formed to a greater depth than has been supposed. To verify this several experiments were performed. A thick film was exposed as usual, then, before development, wetted and a piece stripped from the glass and so developed from both sides. A section showed the laminae to be formed equally well at both developed surfaces. This is shown in Fig. 8, where 150 distinct laminae may be counted. Another experiment consisted in flowing a plate with a thick solution of celluloid varnish, through which, after drying, the exposure was made as usual. On stripping the varnish coating from the gelatine, developing and sectioning, laminae were found all through the film. They are, therefore, formed, with monochromatic light, under the conditions of this work, to a much greater depth than the thickest film used.

It follows from these observations that the small effective number of laminae (about 20 or 30 at the most) is due, not to few being

of film developed with hydroquinone, and should be compared with Fig. 6. Unfortunately, as it seemed at first, the deposit with these developers is black and opaque, making the reflected colour dull in the extreme, and the absorption so great that only few of the laminae are effective. To obviate this difficulty the expedient was adopted of bleaching the film with mercuric chloride. This has been done previously by Neuhauss, and results in a white, very transparent film. The reflecting power of the bleached deposit is not great, so that the luminosity is lost with pyro-developed plates. With plates developed by the three above-mentioned developers this loss of reflecting power is more than compensated for by the greater number of effective laminae. So transparent is the deposit that the absorption is negligible, and all the laminae act with practically equal strength. Consequently, instead of the reflected light being a somewhat diffuse band in the spectroscope it is a narrow

Fig. 8.

Fig. 9.

Fig. 6.

Fig. 10.

formed, as has been assumed, but to the mode of action of the developer. This invited investigation of different modes of development and different developers, from which has resulted a substantial advance in the rendering of pure colours.

Experiments with different modes of development, using the same developer (pyrogallio acid), led to no results. Development with strong developer, with weak slow developer, and with a large proportion of bromide, showed no material difference in the character of the deposit. Long development followed by application of weak Farmer's reducer was unsuccessful, as the reducing solution simply destroyed everything as it slowly worked through the film.

Attention was then turned to other developers, with immediately gratifying results. Ferrous oxalate, glycin, and hydroquinone were tried. All of these developed with great uniformity throughout the depth of the film, without causing fog. Fig. 9 shows a section-

bright line. Moreover, increased thickness with consequent greater number of laminae gives increased purity. Practically, it was found possible to run the films up to about 1-10th mm. (as determined by the number of laminae in sections) with continued increase of purity. A line source is reproduced by such a film as a brilliant line of about 20 A.U. width. By transmission a narrow absorption line appears in the spectrum indistinguishable in a small spectroscope from a Fraunhofer line. In Fig. 14, IV., V., VI., are shown spectra of the mercury green line as reproduced by films containing approximately 50, 150 and 250 laminae. It will be observed that films of this character might serve for sources of comparatively monochromatic light.

The thickness to which the film may be carried is limited by the thickness of gelatine it is practicable to flow and dry satisfactorily. Greatly increased exposures due to the opacity and slow speed of

the thick films made work with them difficult, but the conclusion may be drawn from this work that the purity of reflected colour is, with this procedure, directly dependent on film thickness. It is only a matter of emulsion making and flowing technique to secure films of as high resolving power as one desires.

### Mixed Colours.

Mixed colours, such as two or more spectral lines, or the broad ill-defined bands of the spectrum given by pigment colours, give standing waves which may be compared to the interference fringes

Fig. 14.

they would give in a Michelson interferometer. That is, we have regions in the films where the different wave lengths acting reinforce regions where they oppose each other. The visibility curves,<sup>12</sup> therefore, are applicable to the structure of the Lippmann film. Fig. 1 gives the resultant of two wave-lengths, while the visibility curves figured show the manner in which we may expect the laminae to be distributed for various types of incident light. Photographs have been published by Lehmann showing that the

Fig. 1.

Standing wave system due to two wave-lengths.

resultant structure for two radiations agrees with the calculated. Fig. 12 shows a section of a film exposed to four radiations. The periodic variation in the clearness of the fringes corresponds to the variations of visibility of interferometer fringes.

Two points in connection with the reproduction of mixed colours were studied as of special interest. The first was the question of the degree of complexity of incident light the film is capable of recording. The second was the question of the luminosity values of mixed colours as compared with the component pure ones.

As to the amount of complexity in the incident light which may be reproduced, it is at once apparent that this is dependent on the effective thickness of film. A film developed with pyrogallie acid is, from the previous work, unsuitable where depth is called for, hence the best results in the way of resolving power were obtained from hydroquinone-developed bleached films.

Parallel series were carried out on films of the two types. These consisted in exposures to two, three, and four different wave-lengths, and to a broad spectrum band with sharply defined edges.

With pyrogallie-acid-developed thick films the greatest number of separate wave-lengths reproduced was three, and the result was merely a continuous spectrum with three maxima; four radiations produced ill-defined irregularities. The mercury yellow and green

lines were well separated with such a film and probably somewhat closer lines would be. A sharp spectrum band of 600 A.U. width in the green was rendered as a maximum in the green, but all trace of sharp limits was missing, the reproduction being identical with that of the transmission band of a naphthol green dye solution. This is to be expected, as examination of Fig. 2 shows. The first part of the standing wave system of the two types of colour is identical, and in a thin film, or one whose effective portion is thin, will reproduce as such. The effect of development with pyrogallie acid is, in short, to reduce all colours to one general type.

With hydroquinone developer and bleaching, two, three, and

Fig. 12.

four radiations were reproduced satisfactorily, except for loss in luminosity, the cause of which will be taken up presently. The spectrum band was reproduced with well defined edges. From these tests it was concluded, as with monochromatic light, that the capacity of the film to reproduce any form of complex radiation is only limited by the gelatine thickness possible to be obtained practically.

The second point studied, that of luminosity rendering, will be made clearer by some consideration of the theories advanced as to the nature of the reflecting elements in the film. Lippmann developed the theory on the basis of minute reflecting particles dis-

Fig. 2.

Visibility curves for various sources.

- I. Two monochromatic sources.
- II. Three monochromatic sources.
- III. Spectrum band with sharp limits.
- IV. Type of spectrum of light from most natural objects.

tributed through the film. White, for instance, is due to a continuous irregular distribution of such particles. According to this view all the incident light produces reflecting deposit. Schütt<sup>13</sup> advanced the theory that the action of the light is merely to produce a periodic change in the refractive index. Wiener showed that the reflection in the case of bromide of silver plates was from metallic particles. It is possible, for instance, by exposing films of bichromated gelatine, to secure pictures in which the only change produced is in the refractive index.

The luminosities of all but monochromatic pictures will be ren-

<sup>12</sup> Michelson, "Phil. Mag.," 31, p. 338; 34, p. 280.

<sup>13</sup> "Ann. der Physik," p. 533, 1896.

dered radically differently according to which mode of reflection takes place. For illustration take white. In the one case we have a large number of reflecting particles, in the other a single reflecting surface, practically the surface of the gelatine. A monochromatic source would give many such surfaces through the film with the structureless deposit and would be far more brilliantly rendered than a white visually as brilliant. Where two or three colours act together there are regions of the film in which while the total amount of light action is, say, half the maximum amount, yet sharp changes of intensity are missing. If reflection is due to abrupt change of refractive index these portions would contribute little. A loss of luminosity of the combined with respect to the component colours would result. If this were marked colours with two or more maxima, such as purple or a subjective yellow, would be weakly reproduced. Lehmann, working with superposed spectra, notes such a loss. The experiments which follow were made with the two kinds of development, and because of the large surfaces exposed, and the manner of exposing, critical examination was easy.

The first experiment was to mix two and three colours (red, yellow, green and blue, in various combinations) under such conditions that their resultant intensity when acting together could be compared with their intensity separately. The apparatus used consisted of an opaque line screen, opaque spaces twice the width of the transparent, 100 lines to the inch, which was cut in two and one half turned at right angles to the other. This was placed directly in front of the plate, and by means of a screw could be moved any desired distance in the direction of the lines on one half. This motion caused one set of lines to uncover one third of the surface at a time, the other to continually expose the same strips. In one half would therefore be obtained the three colours superposed, in the other half juxtaposed, in which case the mixing would be visual.

In carrying out this experiment the greatest care had to be taken to avoid the effects of over-exposure. As we have seen, exposure

Fig. 13.

beyond a certain point causes no increase of brilliancy. Hence, if each exposure was a full one we would have the entirely covered surface three times as brilliant (with three colours) as the partially covered, indicating a large luminosity loss in the superposed as compared with the juxtaposed. This was avoided by limiting the exposures so that the total exposure with all colours would not reach the saturation point.

The result of the tests was that with pyrogallic acid the loss of luminosity with two colours, as long as exposure was carefully kept below the saturation point, was hardly noticeable, the only effect being a slight tendency of the superposed colours to shift toward shorter wave-lengths. With three radiations a quite perceptible loss of luminosity was observable. In either case exposure beyond the saturation point caused loss of luminosity. With hydroquinone the luminosity loss was much more marked.

The most instructive test was to expose a plate to light of the green mercury line and to a visual match in colour and intensity consisting of a spectrum band of 600 A.U. width. These gave equal densities in the negative. With hydroquinone development and bleaching the monochromatic side was many times the brilliancy of the other. With pyrogallic acid, the two sides were nearly the same luminosity, the complex radiation only slightly less luminous.

Experiments on photographing natural objects whose colours are for the most part continuous spectra with diffuse maxima, besides showing the necessity for a reflecting deposit, emphasised the necessity of this being of high reflecting power. Very fine grain emulsions proved unsuitable for the production of such colours in

their luminosity values, and satisfactory results were obtained only when the silver content of the film was made as large as would still give colour. The reason is at once apparent when we observe that the colours under consideration give at most only a few laminae near the surface, as shown in Fig. 2, and in the photographed section, Fig. 13. It is necessary not only that the reflecting power of these be large, but that the diffuse deposits behind contribute a share of light in proportion to the light acting to produce it. If the grain is too fine these experiments and work with white light indicate that the separate particles do not act as reflecting surfaces.

The outcome of the experiments is to indicate that with a fairly coarse grain, over-exposure being carefully avoided, developed with pyrogallic acid, there is probably a close approach to the condition of separate reflecting particles. With complex radiation, or with over-exposure, there cannot fail to be a certain amount of fusing together and consequent luminosity loss, and in the underexposed parts there is probably also a loss through the formation of deposit not starting till the light attains a certain intensity. With hydroquinone development and bleaching the reflection is evidently more nearly of the type caused by changing refractive index.

This at once makes evident that for all photography where luminosity values must be preserved, a developer like pyrogallic acid, giving a highly reflecting yet fairly transparent deposit is essential. On the other hand, where complexity of spectral structure is to be reproduced, a deep-acting developer which by proper treatment will give a transparent deposit is desirable.

HERBERT E. IVES.

(To be continued.)

#### CINEMATOGRAPH FIRES.

THE demonstration of the many devices for preventing and extinguishing cinematograph fires (referred to on page 947 of our last week's issue) took place at the London Hippodrome on the 10th inst., before a very large number of manufacturers, dealers, operators, and representatives of insurance companies and the Press. Mr. Walter Reynolds, L.C.C., occupied the chair, and was assisted by a strong and influential committee comprising cinematograph and music-hall proprietors, manufacturers, operators, and officers of insurance companies, whose report may be expected during the next few days. In the arena were fourteen cinematograph machines, and other appliances for extinguishing fires. Mr. Reynolds, in his opening speech, said that the desire of the L.C.C. was not to hamper the industry, but to do all in its power to assist cinematograph work, and safeguard the public. Of the fourteen devices demonstrated, the majority were designed for the prevention of fires, while two of the exhibits were sprinklers of the shower-bath type. Among the exhibitors were most of the well-known firms, such as Butcher and Sons, the Ganmont Co., Charles Urban and Co., Wrench, others. One of the favourite devices appeared to be that exhibited by Messrs. Butcher, with which the operator said, it was impossible for fires to occur. Another popular instrument was that demonstrated by Mr. Bromhead, of the Ganmont Co., and while this was being demonstrated one of the audience asked that the film—100ft. or more—in the fireproof box should be set alight, in order to see what would really happen. Mr. Bromhead at once consented, and set a light to the film. The effect was interesting, as the box was not damaged, and no flame whatever could be seen, but a dense, acrid smoke filled the building. The last "turn" in the arena was a demonstration of the new Lumière non-inflammable film by Mr. T. K. Grant. In conclusion, Mr. Reynolds, who spoke highly of the Lumière film, said that were the new film put into universal use at once, the methods of extinguishing films which had been shown were none the less valuable, as it was impossible to do away with the older celluloid films, which, owing to their immense educational value, would continue to be shown for many years to come. The demonstration was intensely interesting, and should benefit the trade considerably; it also proved that other people besides the L.C.C. are doing their very best to overcome the danger of fires.

MESSRS. RAINES AND Co., St. Mary's Road, Ealing, announce that they will be closing their works from Thursday, December 24, till the following Tuesday, December 29, and will be glad if those of their clients who may have orders for enlargements, etc., to place with them will kindly make a note of this.

## Photo-Mechanical Notes.

### PHOTO-MECHANICAL PATENTS.

The following patents have been applied for:—

**PRINTING PLATES.**—No. 25,934. Improved process for producing printing plates and the like. Eugen Albert, 28, New Bridge Street, London.

**PROCESS ENGRAVING.**—No. 25,968. Improvements in the production of process engraving, process prints, and the like, and in the tools to be employed therein. Joseph Bell, 115, Cannon Street, London:

## Exhibitions.

### KINNING PARK CO-OPERATIVE CAMERA CLUB.

THIS exhibition—the third annual—of the Kinning Park Co-operative Camera Club was held in the large hall, Langlands Road, Govan, placed at the disposal of the club by the Educational Committee. The judges—W. C. S. Ferguson, A. H. Duncan, and John Hepburn—are members of, and were appointed by, the Glasgow Photographic Art Circle, which body had on exhibition their loan panel of members' work. The exhibition is confined to members' work, and, led by that enthusiast, the secretary, the members have made much progress in pictorial photography. The Kinning Park take the credit for displaying the work at their exhibition in a manner second to none of the local societies—canvases coloured screens along each side of the commodious hall being the method employed.

The club is a sworn foe of "pot-hunters," a standing enactment being that, if a picture has gained a prize previous to the exhibition, it is ineligible for competition. The result of this was evident in the number of pictures "not for competition" displayed.

About 120 frames were entered by the members, and a very high standard of work was evident; the intention was always there, if the result aimed at had not always been attained.

The results are as follows:—Landscape and Seascape: Bronze plaques, "Royal Bank Place," William Howat; "As the Shades of Evening Close," James B. Ferguson; "Sunlit Ripples," William Urquhart; hon. mention, George Peebles, Neil C. McLeod. Portrait and figure studies: Bronze plaques, "Marguerite," William Simpson; "Good-night," John Currie. Flowers and Still Life: Bronze plaque, "Star of Bethlehem," Alexander Swan. Outings: Award, "The Village—Evening." Confined to those who have never won a prize:—Outings: Award, "An Evening View of the Clyde," Robert Hutcheson; hon. mention, John Bain. Flowers and Still Life: Hon. mention, Hugh Topping. Any subject: Bronze plaques, "Herring Gutting," Thomas Robertson; "Portrait Study," William C. Stark; hon. mention, James W. Simpson.

### FORTHCOMING EXHIBITIONS.

December 30 to January 2.—Chelmsford Photographic Society. Sec., M. J. Morison, Savernake Lodge, Chelmsford.

December, 1908, to January, 1909.—Kiew International Photographic. Sec., S. T. Horowitz, Technical Society, Kreshtchatik, 10, Kiew, Russia.

1909.

January 1 to 9.—Scottish National Photographic Salon. Sec., Robert Telfer, 138, Glasgow Road, Wishaw.

January 6 to 27.—Northern Photographic (Manchester). Sec., S. L. Coulthurst, Broad Oak Road, Worsley, Manchester.

January 19 to 30.—Glasgow Southern Photographic Association. Entries close December 30, 1908. Sec., Robert Lindsay, 189, Allison Street, Glasgow, S.S.

February 1 to 13.—Glasgow and West of Scotland Amateur Photographic Association. Entries close January 20. Sec., James M'Kissack, 68, West Regent Street, Glasgow.

February 8 to 13.—St. Helen's Camera Club. Entries close January 27. Sec., A. G. Elise, Duke Street, St. Helen's, Lancs.

February 10 and 11.—Cowes Camera Club. Entries close February 1. Sec., E. E. Vincent, 4, High Street, Cowes.

February 20 to March 20.—South London Photographic Society. Sec., H. Creighton Beckett, 44, Edith Road, Peckham, S.E.

February 22 to March 6.—Birmingham Photographic Society. Entries close for abroad January 5, for England, February 12. Sec., Lewis Lloyd, Church Road, Moseley, Birmingham.

March 17 to 20.—Nottingham Camera Club. Sec., E. L. Kent, 5, Radcliffe Mount, West Bridgford, Notts.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for patents have been received between November 30 and December 5:—

**TELEMETERS.**—No. 25,799. Improvements in photographic telemeters or distance gauges. William Wallace Beasley, professionally known as Wallace Bellassie, 63, Onslow Road, Richmond, Surrey.

**PRINTING DESIGNS.**—No. 25,810. Improvements relating to a method of and means for composing photographic printing designs. Adolf Brandweiner, 20, High Holborn, London.

**DISTORTED PHOTOGRAPHS.**—No. 25,828. Improved process and apparatus for producing distorted photographs. George Wutke, 18, Southampton Buildings, London.

**REFLEX CAMERAS.**—No. 25,949. Improvements in or relating to photographic cameras of the type known as reflecting or reflex cameras. Arthur Lewis Adams and Walter George Roberts, Birkbeck Bank Chambers, Southampton Buildings, London.

**CAMERAS.**—No. 25,889. Improvements in photographic cameras. George Sylvester Grimston, 4, Glenluce Road, Blackheath, London.

**VIGNETTING APPARATUS.**—No. 26,115. Improvements in the construction of photographic vignetting apparatus. Alfred Hope Sale, 37, Chancery Lane, London.

**FRAMES.**—No. 26,291. Improvements in and relating to means for applying pressure to photographic frames and for like purposes. Robert Davis Workman, 322, High Holborn, London.

**GLAZING PRINTS.**—No. 26,298. Method and frame for drying gelatine-coated photographic proofs or other papers with the object of obtaining a glazed effect by sticking them on polished surfaces. Nicolaus Ziegler, Chancery Lane Station Chambers, London.

### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

**CHANGING BOXES.**—No. 4,153, 1908. The invention relates to an improved storing and exposing device for photographic plates or films, the device being adapted to be attached to the camera to expose the plates successively as required. The plates are contained in a package or casing of a depth sufficient to accommodate only the whole set, and are each transferred after exposure from the front position to the rear of the last unexposed plate. Hence the package is of as small a depth or thickness as is possible to accommodate the required number of plates or films. The movement of the plates is effected by attached strips or "propellant bands" which pass out through the end of the sheath or package, whilst a sliding cover which when drawn out exposes the front plate also serves as the changing space through which the plate passes in its transfer from the front to the rear of the package. There is a spring on the back of the adapter which will press against the rearmost plate in the package when the cover of the package is drawn out to expose the front plate and to permit of changing plates. This particular arrangement is known in other plate holders in which mechanical devices have been used for moving the plates from the front to the back, but it has not been previously applied to packages of plates worked by propellant bands or tabs. Marian Romanowicz, Rechte Bahngasse, Vienna, III.

**SELF-PORTRAIT LENS CAP.**—No. 19,339, 1908. The cap or shutter consists of a circular spring clip, to which is attached a flap. The flap is brought into contact with the clip by a spring hinge. On

the inner side of the flap is a covering of black velvet or other suitable material to prevent light from entering the lens when the flap is closed. A thread attached to the flap allows of the latter being pulled downwards, upwards, or sideways from the lens. By simply pulling the thread, cord, or wire, the lens is uncovered, and the exposure made. On releasing the thread the flap flies back, and completes the exposure. Frank Dean, 1, Langham Street, London, W.

**APPARATUS FOR ENLARGING, ETC.**—No. 1,328, 1908. The invention consists of an enlarging apparatus in which the negative is illuminated by light reflected from the walls of a chamber (or reflecting hood) in the rear of the negative. The walls of the hood diverge toward the opening and converge toward its opposite or rear end, where they terminate at an opening at which the illuminant consisting of an electric arc, mercury vapour lamp, or other suitable source of light is arranged. The hood may be conveniently constructed of sheet metal and provided upon its interior surface with a coat of white paint, or said surfaces may be otherwise rendered reflective.

The source of the light is, therefore, through the opening in the small end of the hood, the large end thereof, the diffusion plates, and negative, beyond which it is collected by the lens and projected upon the sensitised or other recording screen placed at a proper

focal distance from the lens. Now as both the diffusion plates and the negative are plane surfaces, and since the light emanates from substantially one point, the direct rays alone on the plane surface cannot be relied upon for the purpose in hand, as they would be of unequal strength at different points upon either, and produce corresponding diversity in the image.

The direct marginal rays travel a greater distance than the axial ray, as they travel beyond the arc of which the axial ray is the radius, and are of course therefore proportionately weaker than the latter, as the squares of the distances. But the angles and general arrangement of the walls of the hood are such that the reflected rays are also reflected to points remote from the point at which the axial rays strike the diffusion plate and reinforce the direct marginal rays to a degree of intensity of the axial rays, with the result that the light force at all points on the negative is uniform, and the rays collected by the lens vary only as they are individually resisted by actual passage through the negative. The well-known office of the diffusion plates being simply to disperse the rays in all directions, their interposition is consistent with the foregoing results. Were the provisions for marginal reinforcement not provided, the clouded or darkened effects upon these plates would be communicated to the negative. Kodak, Ltd., 57-61, Clerkenwell Road, London, E.C.

**CINEMATOGRAPHS.**—No. 7,414. 1908. The invention consists of a regulator for the winding device of a cinematograph apparatus, comprising two oppositely arranged conical pulleys, one of which drives the other, variations of the speed of the driven pulley, which is employed to drive the film through the agency of rollers, being produced by displacement of a belt or friction roller connecting the two pulleys, whereby the apparatus can conveniently drive films which are not perforated. This appliance is combined with a film winding or driving arrangement, comprising a driving and a driven shaft, connected through an elastic or yielding coupling, the driven shaft being alternately stopped and released by a suitable retaining device, which is unlatched at the desired times. Claude Marie Gulliet, 26, Rue de la Concorde, Asnières (Seine), France.

**PAPER FOR FERROPRUSSATE SENSITISING.**—No. 26,445. 1907. The invention has for its object the production of a raw paper for photographic purposes, that shall be inexpensive to reproduce, and shall be smooth and tenacious, whilst easily penetrable by the different liquids used in photography without the fibres of the paper being loosened or the sizing injuriously affected.

For sizing the paper, the ordinary commercial size used, as distinguished from the casein size, or the expensive gelatine size, is treated with tanning liquid or a weak acid, which acts on the fibres of the paper, and finally neutralises the paper.

The invention may be carried out in two ways, the paper being sized in the "subsequent" manner and treated with diluted acid or with tanning liquid while still perfectly moist, or the paper thus sized being treated with the diluted acid or tanning liquid after drying.

The paper is then dried in the air, whereby it is rendered very tough by the size, without becoming like parchment, and, which is of special importance, without losing its capacity of absorbing water and the like. This is of considerable advantage, because, in consequence thereof, in the different photographic developing, toning, and fixing baths, the liquid can act likewise from the back of the paper, whereby a quick and uniform toning and fixing of the pictures is effected, and the paper lies perfectly flat in the baths.

Whilst this kind of paper can be permeated by aqueous liquid, different alcoholic liquids have but little effect on it. This is an advantage in papers intended for photographic purposes, as such papers can be sensitised with collodion emulsion without any intermediate layer.

Both kinds of paper can be used for blue prints and photographs, but it is, however, advisable that the raw paper for blue prints should be dried by heated cylinders, the wet process being used. The two processes differ in the choice of the raw material. For paper for blue prints a very cheap material can be employed, whilst for photographic purposes a pure white material must be used. Max Roth, 6, Bogenstrasse, Elberfeld, Germany.

**STEREOSCOPIC CAMERA.**—No. 22,799. 1907. The inventor employs the camera described for making so-called stereoscopic negatives—that is, he obtains "on the negative a picture in relief such as is seen through a stereoscope." A camera is provided with two separate lenses, *a* and *b*—some inches apart from one another—

each of the lenses having at its back the stereoscopic lenses or prisms *c* and *d*—that is to say, lenses similar to those employed in a stereoscope, the arrangement of the lenses being such that separate pictures are taken by the receiving lenses as indicated by

the rays numbered 1 to 4, and are thrown on one another on the sensitive plate *e* and blended into one picture.

The inventor further states that, "with my improved camera, the operator is unable to see the picture distinctly on the ordinary ground glass plate, because it is impossible to have a distant picture on the plate if the picture is meant to be stereoscopic. If, however, the ground glass plate is slightly moistened with oil it gives a good idea of the picture the photographic plate receives. If desired, the ordinary lenses may be dispensed with, and only the stereoscopic lenses used." Franz George Reinke, 55, West Regent Street, Glasgow.

The following complete specification, etc., is open to public inspection, before acceptance, under the Patents Act, 1901.

PRINTING DESIGNS.—No. 25,810. Method of and means for composing photographic printing designs. Brandweiner.

### New Trade Names.

SUNPHAS.—No. 307,712. Chemical substances used in manufactures, photography, or philosophical research, and anti-corrosives. Sissons Brothers and Co., Ltd., Bankside, Sculcoates, Hull, varnish, paint, colour, and oil manufacturers. November 6, 1908.

ARCOGRAPH.—No. 307,337. Prints produced by photographic processes. J. Halden and Co., Ltd., registered offices, 17, Altrincham street, Manchester, Lancs., drawing instrument and material dealers. October 26, 1908.

## Analecta.

*Extracts from our weekly and monthly contemporaries.*

### Remedying Under-Exposed Negatives.

A writer in "Photography and Focus" for December 15, in prescribing partial bleaching with the usual mercury solution as a means of improving under-exposed and over-developed negatives, recommends the following procedure:—

"The negative is bleached exactly as just described, except that the bleaching is stopped as soon as the shadow parts are bleached through. The high-lights, when the glass side of the negative is examined, will still look quite black in colour, showing that the action of the mercury has not extended throughout the deposit there. The negative is then washed as above. As the bleaching action of the mercury goes on to some extent during the washing, it is well to stop the bleaching a little before it seems to have reached the correct stage. After washing, the image is blackened by being immersed in a mixture made by pouring one part of a saturated solution of ferrous sulphate into five parts of a saturated solution of potassium oxalate. The oxalate must not be added to the ferrous sulphate, but vice versa. In this liquid the picture blackens much more slowly than it does in ammonia, usually taking five to ten minutes to complete. The plate is then given three changes in very dilute citric acid (ten grains of acid in five ounces of water is strong enough), and is finally washed under the tap for ten minutes."

The method just described will be found to increase the contrasts of the shadow details much more than it increases those of the high lights, which is exactly what we want. It also has this great advantage over intensification with mercury and ammonia, that if the first application of the intensifier does not prove to be enough, the negative, after being washed and dried, may be submitted to a repetition of the process, and, indeed, to as many repetitions as may appear to be required, only it is essential to dry the plate between each, and to put the dry negative direct into the bleaching bath without any preliminary soaking in water. It is also well to take a trial print before repeating the operation to ascertain whether the intensification has gone far enough. Over-intensification is as great a mistake as over-development.

### Autochrome Lantern Slides.

Mr. Ernest Marriage, writing on the suitable projection of Autochrome lantern slides, in the "Amateur Photographer and Photographic News" for December 15, says:—"Limelight is

deficient in blue rays, and this must be corrected if Autochromes are to be shown with the best effect. This may be done by using a very pale blue screen in the lantern, or by projecting the Autochrome transparencies on to a blue screen. I have found distempers with the trade names "sky blue" or "light blue" answer admirably. Without some correction the blues in an Autochrome do not get due justice done them by limelight. I have a slide of a host of harebells in a wood; on the screen the flowers are hardly visible. Greens, too, in some cases noticeably lose their value.

"Limelight is so much more generally used than the electric arc in lanterns that it would seem worth while to cater specifically for the former. Why should not the makers supply a compensating screen which would pass more blue rays than one which gives correct results for viewing by daylight? This would cut down exposures to some extent, and would enable the lanternist to get the maximum power of the limelight, which, of course, is not obtained if the illuminant is robbed of some of its rays other than blue."

## New Books.

"Fonts and Font Covers." By Francis Bond. London: Henry Frowde. 12s. net.

In this volume, which is a companion to "Screens and Galleries in English Churches," published some six months ago, Mr. Bond traces the history and evolution of the font from the early days of the baptistery and piscina, through the various developments necessitated by change of ritual, to the present time. Whilst the text portion of the book deals entirely with ecclesiastical history, and is in no sense photographic, yet it will doubtless appeal strongly to those photographers who make a special study of church architecture and ornaments, archæology, or record work, for a satisfactory rendering of which an intelligent understanding of the subject is almost essential. The latter portion of the book, dealing with the subject of font covers, is of especial interest, as this subject is practically virgin soil, and the whole volume is, we believe, the most exhaustive treatise on the subject of fonts which has yet been published. The illustrations, 426 in number, are from original photographs secured by the co-operation of photographers and archæologists in all parts of the country, and thus photography plays a not unimportant part in the compilation of this work, on the production of which author, publisher, illustrators, and printers are to be congratulated.

"Who's Who Year-Book," 1909. London: A. and C. Black. 1s. net.

The "Who's Who Year-Book" is made up of the tables which were formerly such a popular feature in "Who's Who" itself. These tables were, in fact, the original nucleus of the book, which developed on different lines into a biographical annual. Thus, though the two books are now entirely distinct, there is an underlying connection, and additional details concerning all persons of eminence who are entered in the tables of the Year-Book will be found in "Who's Who."

The Year-Book was issued in response to numerous suggestions and requests; and the editions already issued have amply proved that, in spite of the large number of reference books, there is still need for one where the information can be seen literally at a glance, and which includes not only the gist of information contained in many expensive publications, but some original tables to be found nowhere else.

Some of the tabs are:—Ambassadors, Ministers, etc., academies (English, Scottish, and French), churches (with temporal heads of each), clubs, House of Commons, Government officials, law officers, London County Council, hospitals, motor-car signs, peculiarly pronounced proper names, heirs of peers, Press, privy councillors, pseudonyms and pen-names, race meetings, railways, schools, societies, university chairs and professors, university degrees and hoods.

"The Englishwoman's Year-Book," 1909. London: A. and C. Black. 2s. 6d. net.

The sphere of women's work obtains the definition of facts in this statistical volume, the sections in which are Education, Employments and Professions, Industrial, Medicine, Science, Literature,

Art, Music, Sports, Public Work, Legal, Clubs, Philanthropy, Temperance, Homes, and Religious Work—truly a formidable list of occupations and livelihoods in which women with greater or lesser prospects of success may engage. We are glad to find that in this paragraph on photography as an occupation for women, a word of warning is uttered as to the over-stocked state of the labour market.

"The Writers' and Artists' Year-Book," 1909. London: A. and C. Black 1s. net.

The staple of the space in this year-book is the directory of periodicals to which literary contributions, photographs, etc., may be offered. In most cases the name of the editor is given, with particulars of the class of matter preferred, and of the terms of payment. The present volume contains, for the first time, a list of the American papers, which are treated in like manner:—The material chiefly required for this market includes short stories, serials, travel articles, gossip about literary persons, essays, etc., but all should be very bright and full of incident or fact; if accompanied by illustrative photographs the matter stands a better chance of acceptance; it should in any case appeal to America and not be viewed from an exclusively English standpoint. Many of the papers will send a specimen copy on approval, so that the style of matter required can be studied. MSS. and photographs should be sent by book post (registered if possible), and letters should go separately.

There are also lists of literary agents and of about a score of photographers who supply pictures and photographs for the illustration of books and articles, but no list is given of agents who undertake the supply of photographs to the Press. The whole production of the volume is clear, and it should be of very great service to those in any way working for the Press.

"Hazell's Annual," 1909. London: Hazell, Watson, and Viney, Ltd. 3s. od. net.

As in previous issues, the contents of "Hazell" are arranged alphabetically, but are very fully itemised in an index, which occupies eleven pages, but is very erratically and irritatingly broken up with advertisements. A regular sequence of pages occupied by advertisements would have been preferable to the irregular placing of these latter, first on the right and then on the left, which has been thus allowed greatly to reduce the value of the indexer's painstaking work. Among the new articles contained in the volume are those on the following:—Aeroplanes, Airships, and Balloons, Agriculture—Small Holdings, "All Red" Route, Baltic and North Sea Agreements, Cables of the World, Census of Production, Coal Smoke Abatement, Co-partnership and Sir C. Furness's Scheme, Cost of Living and Rates of Wages (United Kingdom and Germany compared), Housing and Town Planning, Licensing Question and Statistics, Lotteries and Indecent Advertisements, Naval Forces of England and Germany compared, Old-Age Pensions Act and Regulations, Proportional Representation, Religious Congresses, 1908, Taxation of Land Values, Trade Depression in 1908, Unemployed Question.

But in all the other branches of human activity the volume supplies a most useful précis of progress or of the present position.

"Photographische Chemie" (Liesegang). Third Edition. Re-written by Dr. Karl Kieser. Leipsic: Ed. Liesegang (M. Eger). M.2.50.

This is a book (in German) for the reader who desires an elementary acquaintance with the inner principles of the chief photographic processes, positive and negative. It is not an exhaustive treatise; it is not loaded with historical references; but it is commendably clear and brief in its statement of the chemical bases of operations such as dry-plate manufacture, development, orthochromatising, etc.

"Penrose's Process Year-Book," 1908-9. Edited by William Gamble. London: A. W. Penrose and Co., Ltd. 5s.

The fourteenth volume of this notable production is published earlier than usual this year, and once more Mr. Gamble is to be congratulated on his collection of illustrations and articles. He is, however, not yet to be entirely congratulated upon the get-up of the book. The quiet and tasteful wrapper is in marked contrast to the cover itself, which makes the book look more or less like a Sunday school prize; still the colour and design are perhaps pleasanter than last year.

There are the same great variety of inks, and although there are none so disagreeable as some were last year, it seems to our mind to be more or less a mistake to vary these inks so much. If it is de-

sired to show different kinds of inks, then surely the best way to do that would be to print one block with the various inks, putting it at the end of the book; or, if some blockmakers prefer their blocks printed in a certain shade, then they ought to go at the end of the book. It surely would be more artistic to run one colour throughout, and it is probable that a good black or dark brown would suit most of the blocks very much better than many of the fancy shades shown. Another unpleasant feature of the book is the placing plate illustrations in the middle of an article. There are several articles in which illustrations are interleaved that have nothing whatever to do with the text.

Apart from these few cavillings, we are glad to note that Mr. Gamble continues to use non-surfaced papers, and the paper used this year is very pleasant indeed, though we doubt whether there is not a considerable amount of loading, and whether on this account it would be much more durable than many art papers. Nevertheless it is a good deal pleasanter to handle and look at.

The mass of illustration does not call for any special remark, as the work of photo-engravers appears not to have advanced much further during the past year. There are several examples of work with grain processes, some of the work done with the Metzograph screen being quite excellent. There is also a reproduction in three-colour both by the ordinary crossline screen and by the Metzograph. Certainly, the Metzograph screen shows more texture, but the colours of the two pictures are entirely different, and without knowing what the original is like, the crossline appears to be the more pleasant. There is a Metzograph-screen produced lithograph in five printings, and a photogravure frontispiece, which itself does nothing to deserve the eulogy on the process given by Mr. Gamble in his introductory article, as it looks in the copy we have as though it were printed from a rather worn plate. Altogether there are over sixty illustrations in two, three, and four printings, several from abroad; but, of course, the majority are from England, and again the comparison leaves nothing for the English engraver to feel ashamed of.

In this volume there is perhaps more than usual about lithography and photolithography, the new offset printing presses coming in for attention in two articles, and also electrotyping has a large share of attention. Our friend, Major-General Waterhouse, as well as Mr. Dunton, of New York, and Mr. A. E. Bawtree contribute. Much is said in favour of lead moulding, but something against it also. Autochromes come in for considerable attention also this year.

Among the other contributions, there are two articles from Professor Namias, one on Autochromes, and one on photo-lithography. There is also an article by Dr. Clay on lenses, and one by Mr. Amstutz on acrotones, also one by Mr. Howard Farmer embodying his investigations on the action of the crossline screen, which he gave as a paper to the Royal Photographic Society, and there is a careful argument as to the advantages and disadvantages of grain processes in an article by Mr. A. J. Newton. The editor himself contributes not only the introduction and a summary of the year's progress, but another article on Mr. Payne's new process for photographing direct on metal, which was first noticed in the "British Journal of Photography," and also another article, "Animated Photography in Natural Colours."

On the whole, the volume is marvellous value, and certainly no one who is interested in any of the crafts concerned can afford to be without it.

"Who's Who," 1909. London: A. and C. Black. 10s. net.

It is difficult to say more of the new issue of this indispensable annual than that it now runs to over 2,000 pages, containing over 20,000 biographies, or more correctly autobiographies, since the particulars are supplied and revised by the subjects. Notwithstanding its immense number of pages, the volume is kept within decent limits, and is clearly legible. We number it among our most valuable books of reference.

THE ARTISTIC IMPULSE.—The girl had been three weeks in the family of the amateur photographer with the artistic temperament, but her time had been by no means wasted. Her mistress was giving her instructions as to the dinner.

"Don't forget the potatoes," enjoined the lady.

"No, ma'am," was the reply; "will you 'ave 'em in their jackets or in the hood?"

## Dew Apparatus, &c.

Rodenstock's Universal "Imagonal" Set. Sold by Charles Zimmermann and Co., Ltd., 9-10, Mary-at-Hill, London.

Two sets of these convertible lenses are made, No. 1 being designed for half-plate work and No. 2 for whole-plate. No. 1 is the set we have tried, and its cost, £7 10s., cannot be considered excessive, seeing the wide scope covered by the various combinations. All the changes are made at the back of the objective, and to facilitate matters a so-called "rapid mount" is employed; instead of a screw, a very ingenious kind of spring bayonet joint is fitted. This applies both to the flange and to the back combination, and as a result any required change can be effected in a few seconds. Four back lenses are provided, and with these the following doublets can be formed, each of which fully covers a half-plate:—A wide angle of 5 $\frac{1}{2}$ in. focus and aperture  $f/15$ , a 6in. of  $f/10$ , a 7in. of  $f/6.8$ , and a 10 $\frac{1}{2}$ in. lens of  $f/12$  aperture. All these doublets are anastigmats, and tests show that they are anastigmats of good quality, though not absolutely free from astigmatism like the "Heligonal" doublet. The front combination, used alone, gives what the makers describe as a portrait lens of 8 $\frac{1}{2}$ in. focal length, while if this front combination is unscrewed and the back lenses alone used, then "landscape" lenses of 9 $\frac{1}{2}$ in., 12 $\frac{1}{2}$ in., and 18 $\frac{1}{2}$ in. focal length are obtained. All these single lenses are supposed to be used at  $f/31$ , but larger apertures are available, and may be useful in many cases. The set is put up in a very neat case, carrying also two filter screens, fitting into the back lenses, together with a table of stop values and exposures. It will be noted that the most rapid combination is one of 7in. focus and  $f/6.8$  aperture. This is a very useful type of lens for a half-plate camera, and this particular "Imagonal" is a good anastigmat suited to all kinds of work.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

#### FRIDAY, DECEMBER 18.

Redcar Photographic Society. "On the Printing, Developing, and Toning of Velox Papers." W. F. Slater.  
St. George's Co-operative Camera Club, Glasgow. Dutch Lantern Pictures. A. E. Staley & Co.  
Sutton Photographic Club. "The Movements of the Camera, and their Uses." C. Thwaites.  
Mill Camera Club. Debate.  
Aberdeen Photographic Art Club. Scottish Federation Portfolio.  
L.C.C. School of Photo-Engraving, Bolt Court. "Mark-Smith Etching Machine." G. Venner Dear.

#### MONDAY, DECEMBER 21.

Catford and Forest Hill Photographic Society. Monthly Competitions. Criticism by M. Arbuthnot.

### ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held Tuesday, December 15, Dr. C. E. K. Mees in the chair. A paper was read by Mr. Duncan J. Reid, M.B., C.M., F.Z.S., on methods of photo-micrography. The lecturer dealt in considerable detail with the installation of a photo-micrographic outfit and with the procedure for finding the numerical aperture employed. On this latter he based a standard of exposure for normal subjects, explaining that in the case of stained objects and others of a special character there is no other means except the worker's personal judgment.

### THE PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

A MEETING of the General Committee was held at the Royal Photographic Society, 66, Russell Square, W.C., on Friday, December 11. Present: Messrs. Alfred Ellis, Lang Sims (Hon. Treasurer), H. C. Spink (Brighton), and A. Mackie (Hon. Secretary). Mr. A. Ellis in the chair. The Hon. Secretary read correspondence between the Hon. Secretary of the Newspaper Society and himself in reference to the arrangement of a conference for the purpose of settling a recognised form of procedure with regard to the use of photographs by the Press, for which permission to reproduce had not been previously obtained.

Letter read from Mr. A. A. Bridge in reference to an interview the writer had had with the manager of the Platinotype Co. at the request of the committee on the subject of discount terms on platinotype paper.

Letter read from the manager of the Fine Art and General Insurance Co. in reference to the insurance of extra hazardous structures.

Correspondence read between the Hon. Secretary and Messrs. Welchman Bros., of Retford and Gainsborough, members, relative to the prosecution of a free portrait canvasser, who had obtained orders on the representation that Messrs. Welchman were giving the enlargements away for the purposes of advertisement. The action taken in the matter by the Hon. Secretary was confirmed.

The Hon. Secretary was instructed to write to Mr. W. Downey a letter expressing their sympathy in the loss of his son, Mr. W. E. Downey.

Several other matters relating to the business of members were also dealt with.

MELBOURNE CAMERA CLUB (DULWICH).—Thursday, December 10, was the date appointed for a committee to consider the formation of a concert to be given in January. Some four to five hundred persons are expected, and the programme will have some leaning towards photography in the form of a lecture during the interval demanded by the artists, to be delivered by Mr. Visick, the Secretary, entitled the "Lusitania" and "Mauretania." A somewhat novel item will present itself in the manner of engaging three children to distribute souvenir postcards of the club. The children will be attired in artistic dresses made up of the covers of the "B.J." and those of two of its contemporaries, constituting red, white, and blue, to represent the Press and our national colours. Following this committee was the general meeting, when the President gave the second of his elementary evenings on "Exposure and Development." M.Q., Amidol, and Rodinal were discussed at length.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—At the meeting held Thursday, December 10, Mr. T. E. Freshwater in the chair, Mr. W. R. Stretton read a paper upon "Art and Photography."

GLASGOW AND WEST OF SCOTLAND AMATEUR PHOTOGRAPHIC ASSOCIATION.—This society will hold its annual exhibition at 180, West Regent Street, Glasgow, from February 1 to 13, 1909, when Messrs. J. Craig Annan and R. M. G. Coventry will perform the work of judging the exhibits. In the open classes, three in number, one will be entirely devoted to autochromes, and the specially designed association plaque will be placed at the judges' disposal for award. Entries close January 20, on or before which date entry forms, together with the necessary fees, must reach the Hon. Sec., Mr. J. M'Kissack, 68, West Regent Street, Glasgow, from whom entry forms and further particulars may be obtained.

## Commercial & Legal Intelligence.

**THE LUXIA COMPANY.**—(George Frederic Turtle, lately trading as manufacturer of sensitised paper, late of 14A, South Hill Park, Hampstead, N.W.) The statutory first meeting of creditors under this failure was held on December 14, at the London Bankruptcy Court, Mr. Egerton S. Grey, Official Receiver, presiding. The receiving order was made on November 30 upon the petition of Otto Scholzig, the act of bankruptcy alleged being the debtor's non-compliance with the requirements of a statutory bankruptcy notice. The chairman reported that, according to the debtor's statements, he for ten years prior to 1901 financed his son-in-law, Mr. M. S. Berger, who was carrying on business as a sensitised paper manufacturer. In that year he purchased the business at the price of £600, and had since carried it on at 14A, South Hill Park, Hampstead, under the style of the Luxia Company. For the last twenty years he had also been engaged as an insurance agent, and as an inspector had been in receipt of a salary of £200 per annum. He had not taken any active part in the business of the Luxia Co., the management of which he left to his son-in-law. Later, however, the business had been managed by another person. The debtor further stated that on October 16 last he sold the business for £750 in debentures of a company to be formed for the purpose of acquiring it, but the company was never formed, and the business was then sold to another person for £750 in bills. No valuation was made, but he considered that the sale was a fair one at a forced sale. His son-in-law had instituted proceedings against him, claiming to be a partner in the business, but those proceedings were dismissed; another action had, however, since been commenced. The debtor had not filed any statement of affairs, but he estimated his liabilities at £750. He denied that he was insolvent, saying that, if the bills for £750 were duly met, he should have enough assets to pay the creditors 20s. in the £. In addition, he disclosed assets in the shape of nine freehold houses, mortgaged for £2,400, the surplus value of which was doubtful, and £25 in cash.

On behalf of the debtor it was pointed out that he did not receive a shilling profit on the sale of his business, which was simply disposed of for a sum exactly sufficient to pay the liabilities. Mr. Berger's claim for £792 was disputed. It was believed that the bills for £750 would be met in due course. The debtor was quite willing to consent to an order of adjudication.

The chairman having admitted the proof of Mr. Berger for voting purposes to the extent of £35 odd, a resolution for bankruptcy was passed, and Mr. Henry Fraser, chartered accountant, appointed trustee to wind up the estate. The following committee of inspection were nominated:—Messrs. Otto Scholzig, M. S. Berger, and Otto Rosenstheim.

The debtor's public examination is appointed for January 12.

Appendix is a list of the principal proofs of debt lodged by creditors:—

	£	s.	d.
Berger, M. S. ....	792	9	5
Golding, E. H. ....	420	9	7
Golding, J. ....	39	5	7

Scholzig, O. ....	202	10	1
Wright Bros. ....	10	0	0
Nelson, Dale, and Co. (Ltd.) ....	16	8	0

**THE POST OFFICE AND ART PHOTOGRAPHS.**—At the South-Western Police Court, on Saturday, Mr. de Grey finally dealt with the two summonses against Hermann Karl Wilhelm Erdmann, trading as Erdmann and Schanz, photographic publishers, Bedford Hill, Balham, alleging that he had sent postal packets containing improper portraits through the post. The case has already attracted a good deal of attention in the daily press, but the summing up of Mr. de Grey, as reported in the "Times" on Monday last, contains the arguments for and against the classification of the photographs as "indecent."

Mr. de Grey, in giving judgment, said the proceedings were taken under Section 4, sub-section (b), of the Post Office Protection Act,

1884. It was admitted that the defendant sent two packets, the one addressed to a Mr. Fitzpatrick, the other to a Mr. Hawkins, in Tasmania, containing photographs and other documents, which were seized in Tasmania and returned to the General Post Office in this country, where they were examined, and thereupon the prosecution was instituted. The question, therefore, that he had to determine was whether the photos were or were not indecent. It would hardly be contended by the defence that if these photographs were exhibited in a shop window or sold openly in the streets or across the counter of a shop they would not be indecent photos. The Post Office authorities, indeed, laid down the proposition that certain photographs were necessarily indecent. It was not necessary for him to assent or dissent from that proposition absolutely, for reasons which he would give. He would go so far as this, that if photographs of this character were sent by post it must lie on the defendant to justify the sending of them and to show, if he could, that, under the peculiar circumstances of the case, they were not to be classed as indecent, that was, calculated to corrupt the morals of those into whose hands they might fall. The defendant's contention was that he supplied these and similar photographs for artistic purposes only, and only to artists and artistic students, and he contended that, if intended to be sent to such persons and for such purposes only, they were not to be classed as indecent, and in support of this proposition he called several artists, sculptors, and others, who gave it as their opinion that the photographs were not indecent, and that they had used or known to be used similar photographs for artistic purposes. But when he came to look at the photographs themselves he found that, though some of the larger ones which were in Mr. Fitzpatrick's packet might be said to be artistic poses, two at least were in distinctly suggestive and inartistic attitudes. With regard to those in Hawkins's packet, there were a great variety of attitudes, some of which might be classed as artistic poses, but many of which were inartistic and suggestive. He thought, therefore, that even if the defence made out that the photographs were intended for artists only they would still be unable to resist the accusation of having sent by post photographs which were, in fact, indecent. And the defendant must be taken to have intended the natural consequence of his acts, and he must, therefore, be taken to have sent the photographs with a wicked intention. But had the defendant in his evidence made out even that he intended the photographs for artists or art students only? He said that he made inquiries with regard to his customers, but it seemed that these inquiries were only as to their solvency, or what he termed their bona-fides, through Stubbs's Agency. As regards Hawkins and Fitzpatrick, the only evidence of their being artists was a passage in the letter of one of them, in which cloud studies were mentioned, and the defendant says that only an artist would talk of such things as cloud studies. This was rather a flimsy pretext for considering a man to be an artist or art student. In fact, he knew him to be a tea merchant, and that was all. And when one looked at Fitzpatrick's letter it was quite evident that he, at any rate, did not require these photographs for artistic purposes, but for something totally different. With regard to the objection taken at the close of the prosecution that each of the two summonses should have been heard separately, and that the prosecution should have elected on which they intended to proceed, he entirely disagreed. Two summonses, he said, were applied for, and, as was frequently the case when the summonses related to one offence, they were tried together. The defendant could not be prejudiced, because it would be no defence to a prosecution in the case of Hawkins's packet to plead that he had already been convicted in the case of Fitzpatrick's packet, or vice-versa. He therefore convicted the defendant, and fined him £10 and five guineas costs in each case, £30 10s. in all.

**WALTURDAW COMPANY, LTD.** (Cinematograph Manufacturers, London).—A memorandum of satisfaction in full of debentures, dated August 23, 1906, securing £2,000, has been filed.

**LEGAL NOTICES.**—A first and final dividend of 5s. in the £ is to be paid in the case of Mrs. Mary Ann Osguthorpe, photographer, Falconer's Road, Scarborough.

Notice of an intended dividend is given in the case of George Robinson Harris, carrying on business under the name of G. R. Harris, and also under the name of Harris and Co., photographers etc., 222, Broadway, Bexley Heath, Kent. The last day for receiv-

ing proofs by Mr. Tatham, Official Receiver, Maidstone, is December 22.

An adjudication order, dated December 8, has been made against Samuel Thomas, photographer's assistant, of The Mount, Pearson's Road, Birkenhead, lately residing at 113, Camden Street, Birkenhead. Debtor filed his petition the same day as the order.

Notice is given in Saturday's "Government Gazette" of the voluntary winding up of the Animated Photograph Company, Ltd. Mr. H. C. Bound, 57, Moorgate Street, E.C., is the liquidator.

## News and Notes.

**PHOTOGRAPHS OF PRISON SCENES.**—An excellent instance of specialisation in photography is afforded by last week's "Sphere," which contains an article and nearly a score of photographs of scenes and incidents in the female prison at Aylesbury, which is the only convict prison for females in this country, and has never previously been photographed for any publication purpose. The photographs are the work of Mr. H. Andrews, of the firm of Bulbeck and Co., by whom also a large series of negatives has been made in the Wormwood Scrubs Prison. Photography in a prison calls for technical skill of a peculiar kind, but the photographer in these instances has been able to take advantage of the unique facilities which have evidently been granted him.

**NOTTINGHAM CAMERA CLUB.**—The eighth annual exhibition of this society will be held from March 17 to 20, 1909, in connection with which the authorities announce that they are prepared to collect pictures from Birmingham and forward them to Sheffield free of charge to exhibitors, if desired. Entry forms are not yet to hand, but further particulars may be obtained from the Exhibition Secretary, Mr. E. L. Kent, 5, Radcliffe Mount, West Bridgford, Notts.

**COWES CAMERA CLUB.**—This club will hold its second annual exhibition in the Town Hall, Cowes, I.W., on February 10 and 11, 1909. There will be six open classes, one specially devoted to colour work (prints or transparencies). Bronze plaques and medals will be placed at the disposal of the judge, Mr. S. G. Kimber, F.R.P.S., for award, together with a silver challenge plaque for the best picture in the exhibition. Entries close February 1, and further particulars, with entry forms, may be obtained from the Hon. Sec., Mr. E. E. Vincent, 4, High Street, Cowes, I.W. Exhibits intended for the exhibition of the Isle of Wight Photographic Society will be conveyed from Cowes to Newport free of charge.

## Correspondence.

\**Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

\**We do not undertake responsibility for the opinions expressed by our correspondents.*

### CARBON PRINTING ON IVORY BY SINGLE TRANSFER.

To the Editors.

Gentlemen,—The difficulty of cleaning off the single transfer carbon image after drying, combined with my own long experience of the process, convinces me that any fear of want of adhesion of the once dried images is entirely mistaken.

The use of a substratum in a single transfer process would at once destroy its special advantage, that of offering the artist a real ivory surface to work upon.

As I understand it, a single transfer process on ivory was attempted commercially many years ago, but abandoned, not from any want of adhesion of the completed image, but from the impracticability of removing the bichromate stain; the process of washing the tissue completely, and then extracting the water with alcohol, not being then known. If, however, there is any record of such use it would be interesting to know where it may be found.—Yours obediently,

W. E. DEBENHAM.

[Our correspondent is quite mistaken in supposing that the single transfer method was abandoned—or rather not put to commercial use—because of the staining of the ivory, as that is impossible when

the bichromate is washed out of the tissue. It was because of the slight adhesion of the film of the finished picture to the ivory. Whereas by the double transfer method, as described by us in these pages, it is impossible to disturb the image except by scraping it off, or by treatment with very hot or boiling water. It goes without saying that after washing out the free bichromate it makes no difference whether the tissue is allowed to dry spontaneously or has the drying hastened by spirit.—Eds. "B.J."]

### LARGE VERSUS SMALL SIZES: A BUSINESS QUESTION

To the Editors.

Gentlemen,—Of late years there seems to us to have been a tendency to cultivate business in the wrong direction, viz., by giving prominence to portraits of small-size post-cards, midgets, and the like at cutting prices, instead of working in the opposite direction."

After reading this paragraph on page 938 of the "Journal's" last issue, I scanned the advertisement columns, and what do I find? Every page crowded with adverts. re midgets, post-cards and devices, "multi" this and "multi" that, for turning such out by the million, and also in "Situations Vacant and Wanted," every assistant must be, or is accustomed to large quantities, skilled in midget work and post-cards; must be willing to work on a Sunday, and be used to night work. Thus, does this "Journal" give prominence to that which the editorial article decries; but, I presume, its advertisement pages are but the mirror which reflects the status of the photographic art.

Oh! Shades of all the mighty workers of the past, whose names I could pen by the dozen or so. How our art has fallen. But I have no wish to repeat my views on the subject; they have appeared often in these pages in a Gilbertian strain.

"Lord Chancellors were as cheap as sprats,  
And Bishops in their shovel hats  
Were as plentiful as tabby cats,

And dukes were three a penny."

But may I add that the few thousand midget cards which an eloquent and plausible traveller induced me to order some seven or eight years ago (and which I have never attempted to use) I have burnt. Again, to quote from the paragraph in question, "A single picture of these sizes (12 x 10 or so) carries as much or more profit to the photographer than do, perhaps, several dozen of the smaller sizes." In face of this, may I state, that you can have in this town a sitting and one copy, 12 x 10 size, for the munificent sum of 1s. This is a fact, and is well advertised by the producer, in addition to the advertisement I hereby give him. The president of the Royal Photographic Society in the same issue, page 950, says: "The triumphs of photography have been those of commercialism." Rather a hollow sort of triumph, is it not?—Yours faithfully,

The Studios, 7 and 8, Park Street, Hull.

W. BARRY.

To the Editors.

Gentlemen,—Your article in to-day's issue is just what the middle-class man should put into practice. For some time now I have been making a show of Imperials, and gradually people have taken to them. Just now I am doing quite a number for Christmas, taking direct. I never do postcards under 4s. per dozen, and then only full or three-quarter length, and never exhibit same in any way prominently. I have any amount of good men competing with me in my town, and I notice they show the same specimens for months together. I always change my show every week. A lady said to me only to-day: "I never see anything fresh or new in any of the big men's windows." I am only a middle-class struggler, but I think I struggle on the right lines. I enclose my card.—Yours truly,

A TRIER.

### STEREOSCOPIC PROJECTION.

To the Editors.

Gentlemen,—I was much interested in the letter by Mr. Harry de Beer in the "B.J." of last Friday, 11th inst., and so would be much obliged if you would just add one word of explanation to the *modus operandi* described. He says, "The slides were then washed in soda sulphite solution (what strength?), and then fixed in hypo." Does this mean to say that all the previous dyeing operations were performed before fixing, therefore in the dark room, or were the lantern slides made as usual and then dyed?

if so, what is the second fixing for? Then no definite instructions are given as to the strength of the various solutions mentioned.

Now let me point out just one thing lacking here, and also in your valuable "Almanac": A solution of iodine in iodide of potassium is frequently mentioned, but in the present "Almanac," as in those of previous years, the making of that solution has not been given. Is it a saturated solution of potass iodide or a 10 per cent. solution? And then how much iodine is dissolved or can be dissolved? At what strength is it used as a clearing bath? Although I have noticed it is not given in the "Almanac" as such, though used for that purpose in negative making).—Yours faithfully,  
A. THOMAS,

340, Hungerford Road, Crewe.

[Perhaps our previous correspondent, Mr. Harry de Beer, will be agreeable to supplement his previous letter with particulars of the solutions used. We may point out, however, to the writer of the above letter that the fixing bath is used by Mr. De Beer to remove the silver iodide formed on bleaching the iodine; an image in dye only is thus left, and the process, subsequent to the first preparation and fixing of the lantern transparencies, need not be done in a dark room. In regard to the use of a solution of iodine in potass iodide, the only two instances we can turn to at the moment are on pages 787 and 808, in both of which a 10 per cent. solution of iodine is directed. The quantity of the iodide, provided it is sufficient, is immaterial, an excess having no effect on the employment of the bath for the reduction of negatives or bromide prints. A useful method to adopt is to place the iodine in an empty measure, add about twice or three times its bulk of potass iodide, and then just enough water to allow of a fluid mixture being made. The iodine will then dissolve immediately, which it will not always do when stirred up with a comparatively weak solution of iodide.—Eps. "B.J."]

#### AGREEMENTS WITH MANAGERS OF BRANCH STUDIOS.

To the Editors.

Gentlemen,—In the "Daily News" of a fortnight ago there appeared an article headed "An Evil Practice," dealing with radius agreements, in which the writer said:—"The injury caused alike to the employees and the public by such is very great. Their tendency is to stifle competition and practically to hand over a monopoly of the trade to existing firms." Will you allow me, in your valuable paper, to show the fallacy of this argument, because I believe that photography has materially suffered through the non-application of the principle.

I am as strong an advocate of free trade as probably you are, and I say one man has as much right to live in a town as another, providing he gets established there on equitable lines. One of our leading men not long since remarked that it was competition versus co-operation which was damaging to trade. Now as I understand the radius agreement principle it is this:—You employ a stranger to come and conduct, say, a branch business you have purchased from a trader in another town. He comes, and finds the business wants energy and push, and you agree to pay him accordingly for his work. Perhaps for months, it may be a year or two, or even more, the margin of actual profit is small, if any. It then begins to grow. In another year this manager says things are paying well now; my work has become known and I have made many friends; I shall now start on my own account. He can do this with impunity if you have no agreement; but if you have, surely it should be enforced. Oh no, the writer says, it is injurious to the public. I deny it. The only one injured is the man who has invested his money and run the risk of success for two or three years. You do not stop competition merely by your agreement. Any stranger may come the week after you bought it and start another, or at any future date. What you object to is having your own house divided. If your manager wishes to start de novo he is free to benefit the public anywhere else, as free as you were to take the risk of a branch business where you were unknown. It is to prevent this kind of division radius agreements were made. But how has photography suffered? Perhaps most in provincial towns. The competitors, to make a living, have begun reducing prices, and this has grown, and so you may find in some fairly large towns I could name a dozen cabinets offered for 5s. 6d., and a dozen photographers trying to exist on a population of 10,000. Probably three or four of them do, but as for the rest the less said the better.

OBSERVER.

## Answers to Correspondents.

### PHOTOGRAPHS REGISTERED:—

G. MESS, The Priory Studio, Church Street, Christchurch, Hants. *Photograph of the Priory Church and Ruins, Christchurch, in a Snow-storm.*

MEASUREMENT OF FOCAL LENGTH.—In describing Grubb's mechanical method of ascertaining the equivalent focus of lenses, Mr. Traill Taylor, in his "Optics of Photography," p. 103, lines 9-11, says:—"The distance of the intersection of the first two lines and the third line is the equivalent focus of the lens." I shall be glad if you will say if, in your opinion, Mr. Taylor meant the distance between the apex of the triangle formed and the intersection of the base line with the containing sides of the angle or the distance between the apex and the nearest point (the centre) on the base line.—J. W. B.

The distance from apex to centre of base line is the correct focal length.

COPYRIGHT.—A few months ago I photographed a certain subject, but finding that a local tradesman has had reproduced this particular subject from my original, and without my permission, I have this week registered same. What can I now do in the matter to stop further sales? I do not know the firm who reproduced same. Can I legally demand to know, or is it sufficient to warn the one who had same reproduced?—COPYRIGHT.

Now that registration has been effected you are at liberty to take action against either those making or selling the reproductions. Both are equally liable, and a solicitor's letter to the latter should be sufficient to cause him to withdraw the goods from sale.

J. ARGENT.—(1) About 10,000 on a rough estimation. (2) There is not one. (3) Apply to the Secretary, Mr. A. Mackie, 89, Albany Street, London, N.W.

POLYCHROMATIC EMULSION.—I have reason to believe that I can colour the silver haloids in gelatine emulsion in the three colours enclosed, so that each will retain its colour when in emulsion form. Would the result be colour in the negative and positive, or what would be the probable result? The colours are not soluble in water. The green and violet in powder form are sensitive to light. They are the common dyes sold in penny packets put through a very peculiar process, which alters their nature. I have enclosed a small sample of the green in powder form. If exposed to sunlight for a time it will gain in colour. My reason for writing to you is, will it pay me to go on with the experiment, as I have none too much money but plenty of time on my hands? Kindly give me your opinion.—W. R.

It is useless your attempting to dye the emulsion with colouring bodies which are not soluble. Apparently the lines on which you are working are those suggested in an article by Schinzel which we published in the "Colour Photography" Supplement to the B.J. of August 7, 1908, p. 61. As we then pointed out, the technical difficulties in the way of such a process are very great. If we knew more definitely what you are driving at we could, perhaps, advise you.

W. S., Junr.—(1) We advise you to get a lens made specially with a view to its use in this way, such as the Aldis "Trio" or "Duo." See page 716 of the "Almanac." (2) We have no experience of the shutters you name. The "Goerz" sector is very reliable, and we advise you to pay a good price if you want a reliable shutter of this class.

TRIPOD.—A special and very good pattern is made by the Thornton-Pickard Manufacturing Co., Altrincham, Manchester. Possibly they would make another pattern in quantity.

W. E. C.—It is not easy to give a satisfactory explanation of the reversal, if, as you say, the films were developed in a machine, for the most likely cause is exposure to actinic light during development, a stronger positive image being printed from the primary negative image. We have known this to have caused the defect in other cases.

COPYRIGHT.—There is a humorous picture, consisting of two children, published and copyright in New York (America) (and, I take it, to be copyright in this country). An artist showed me another picture of the same children in an entirely different attitude bearing the same title, but with a different meaning to it. What I wish to know is:—(1) Could this picture be made copyright

here, also in America (if so, what is the best way to proceed with it, and what would be the cost?), or would it be infringing their copyright? (2) Would it be better to submit to them a rough sketch, and inquire if they would be willing to publish it provided the matter has been satisfactorily settled; but, by doing this, what I am afraid of is that they may take the idea from it, and publish it without even troubling to communicate?—COPYRIGHT.

If the second picture is a separate original work of art, certainly it is entitled to copyright, and can be registered here in the usual way at Stationers' Hall. We cannot say whose property the copyright will be, as you tell us nothing of the commercial circumstances of its production.

**PYRO-SODA DEVELOPER.**—I shall be glad of your advice in reference to the following developer:—

A.—Pyro .....	110gr.
Met. potass .....	20gr.
Soda sulphite .....	2oz.
Water .....	20oz.
B. Soda carbonate .....	2oz.
Potass. bromide .....	15gr.
Water .....	20oz.

A., 1oz.; B., 1oz.; water, 2oz. Would you please tell me if the above would give the developer in accordance with your suggestion at the end of the article on "Pyro Soda Formula" in your "Journal," December 4? If not, kindly state what would. —"H. B. B."

Your formula has its constituents in the following proportions when applied to the plate:—

Pyro .....	1.4gr.
Potass. metabisulphite .....	1gr.
Soda sulphite .....	11 gr.
Soda carbonate .....	11 gr.
Potass. bromide .....	1.5gr.
Water .....	1 oz.

which, as you will see, is a good deal too weak to give the average formula given on page 922 of our issue December 4. The stock solutions (to be used in the ratio of A, 1; B, 1; water, 2) to give this latter are:—

Pyro .....	220gr.
Potass. metabisulphite .....	40gr.
Soda sulphite .....	4oz.
Water .....	20oz.
Soda carbonate .....	4oz.
Potass. bromide .....	30gr.
Water .....	20gr.

**J. W. HART.**—You use too much water. Dissolve the one ounce of pyro in 5oz. only, using twenty drops of nitric acid. Also we imagine the water is more fully aerated than is well. Try boiling it vigorously for five minutes in an enamel saucepan, and using when cool.

**GLAZING POSTCARDS.**—(1) I find that postcards will not come off the plate glass. I followed the instructions, except adding the dissolved alum to the hypo mixture before the hypo was fully dissolved. Would this error account for it? (2) A friend tells me that the fumes of a gas-stove cause metal articles in the room to rust very quickly. Is this correct?—"ENTHU."

(1) The premature addition of the alum should not have the effect described. Improper cleaning of the plate-glasses is a very common cause of sticking. We suggest that if proper polishing with French chalk does not improve things, you should use a chrome-alum fixing bath, such as that on page 780 of the "Almanac" (1909). (2) Both the gas and the stove would have to be very bad for such an effect to be produced. A certain quantity of acid is generated where gas containing much sulphur is burnt, but gas companies now manufacture under strict supervision, as a rule, and, in any event, a gas-stove is usually so fitted that the products of combustion pass up a flue.

**TONING BROMIDES.**—(1) What toning bath for bromide postcards could I employ so as to get a tone resembling P.O.P., the same as on trade cards? (2) Is there a paper called the "Practical Photographer," and, if so, what is its price and whom published by and at what periods?—"TYNWALD."

(1) It is difficult to get a tone imitating that of P.O.P. by toning bromide cards. We should think that possibly the new "Ensyna" paper, described in our last issue, would enable you to do what you want. (2) The paper ceased publication some months ago. It was issued monthly, price one shilling.

**COLLODION P.O.P.**—I am enclosing print, which, as you see, is spotted all over. This trouble has occurred very frequently of late, in spite of every precaution being taken in washing and all operations connected with toning and fixing, etc. The paper is C.C., toned in gold bath and platinum. May say that I do the whole of my printing and toning myself, and feel sure all precautions have been taken to avoid this trouble, but have not been able to quite free myself from it. The prints are washed by hand thoroughly, and then in running water all night, and mounted with "Photo Stickphast." Any suggestion that would help free me from this trouble would be gratefully accepted by yours faithfully,—OPAL.

We should not wash so long as the eight or ten hours which you must be giving at present. One point of great importance is to dry prints quickly after mounting. Neglect of this is liable to cause the epidemic of spots you describe. We would further refer you to the articles on precautions necessary in C.C. printing, which appeared in the "Almanac," 1906, pp. 786-789.

**D. M. EDWARDS.**—Apply to Messrs. Dawbarn and Ward, Ltd., 6, Farringdon Avenue, London, E.C., for their full list of photographic works.

**MEDIUM AND OTHERS.**—In our next.

**C. NYE.**—Try Mander and Sons, Branstons Street, Birmingham, or H. Cornthwaite, Dale End, Birmingham.

**B. DOS SANTOS LEITAO (LISBON).**—The apparatus is the only one of the kind with the great range of movements (rise and swing) on the front. It is quite equal to the other manufactures of the firm, but is so distinct in design from the other patterns referred to that it can hardly be compared with them.

**SILVER STAINS.**—1. Could you kindly tell me a preventative of silver staining on negatives? 2. Would it cause them to stain by keeping them in a warm kitchen?—A CONSTANT READER OF THE "JOURNAL."

1. Use a very resistant varnish, such as the Vitri-vine, of the Vanguard Manufacturing Co. 2. No, unless the place is also damp. A warm, dry place is as suitable as any for either varnished or unvarnished negatives.

**J. O. ALDER.**—We cannot say. Why not write Mr. Pfenninger, whose address is 105, Hythe Road, Brighton?

**J. E. G. (LT.-COL.).**—The enlargement seems to us to have been unequally lighted, and to have been fogged either by light or developer. We can hardly say more without seeing the negative, but the latter would not appear to be the cause of the defect.

**BROMIDE.**—The commercial work is done, in the case of large batches, by the hypo-alum process. We know of no cheaper process.

**E. F. R.**—On the whole the specimens are fairly good. But they are not such as required in a first-class studio. The fact that you have had three engagements within the year does not look as if you gave entire satisfaction in them. At the age of twenty you must not expect the same salary as men of more mature age, of whom so many are now out of employ. Whether or not you should persevere in the photographic profession or seek some other avocation, you and your friends are better qualified to answer this question than we are. The specimens have been returned as requested.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## The British Journal of Photography.

The Oldest Photographic Journal in the World.

ESTABLISHED 1854. PUBLISHED EVERY FRIDAY. PRICE TWOPENCE.

## SUMMARY.

The index to "The British Journal of Photography" for 1908 and for the "Colour Photography Supplement" for the same period is presented as a supplement to this issue.

The Christmas Holidays.—The publishing and advertisement offices of "The British Journal" will be closed on Friday and Saturday next; on Monday postal business will be attended to. The editorial offices will be closed until Tuesday morning.

Royal Photographic Society. Some extracts from a document relating to the internal affairs of the Royal Photographic Society are given on page 982.

The concluding portion of the article by H. E. Ives on the Lippmann process of colour photography is given in this issue (pp. 979 to 982). Mr. Ives has worked out a substitute for the mercury mirror, which allows of the Lippmann process being practised with ordinary dark slides.

A movement has been set on foot by Mr. Reginald Craigie to establish a camera club in the west-end of London. (P. 978.)

Dry-mounting, enlarging lanterns, and a coin-in-slot camera are among the patents of the week. (P. 984.)

We refer in an editorial article to the question of agreements made between photographers and assistants acting as branch managers. We shall be glad to hear the views of any interested. (P. 978.)

Two most enjoyable functions of last week were the Houghtons' smoking concert (P. 989) and the students' supper of the Bolt Court School. (P. 992.)

## EX CATHEDRA.

### The Compliments of the Season.

We cannot allow the present year to depart without offering to our readers at home and abroad these greetings customary to the season. Universal as this exchange of salutations is throughout Christendom, it has, perhaps, much less formality in the case of the editor and readers of a technical journal than in many other relations. We are brought into direct communication with many of our readers during the course of the year; we have not failed to appreciate the marks of their friendly feelings, and we are encouraged to hope that among a good proportion such sentiments are reciprocated. And, therefore, at the time when we write "Finis" at the foot of another volume of the "B.J."—but not in any sense by way of indication of any cessation of its activity and independence as a photographic journal—we are glad to take the occasion of wishing all our good friends a prosperous and profitable year during 1909.

\* \* \*

### The Index to the 1908 "B.J."

It was a lady in one of Mr. Barrie's plays, if we remember rightly, who presented her husband with cigars of a new brand, remarking that they were larger than those he was smoking, a point of view wherefrom a contemporary once elected to regard an index to its annual volume, with the laudable object of discovering some respect in which it might be said to possess distinctive excellence. Our own aim being to make the index a key to the contents of the volume, we have further done all that seemed possible to reduce the weight of the key, to give it the handiness of that of a Yale lock in preference to the bunch jangled by a Wilfrid Shadbolt. And so, if the present index is less in size than others, we crave your patience, good friends, that you first discover wherein it fails to point to various items contained in the volume now closing.

\* \* \*

### Index by Subject.

As we pointed out last year, it is advisable that an indexer should indicate one or two rules to which he has adhered, and which a user of the index may bear in mind in looking up an item. An important one is to bring all the items on a given subject under one heading, and to attach cross references to this main section to any others which cannot be brought readily into line. Thus, "Screen Plate Colour Processes" are indexed as "Colour Photography—Screen Plate" in the main section, and separate references attached to entries such as Autochrome, Thames, etc. On the other hand, where the sub-division of a subject turns out to be larger than the subject itself, a separate series of items is transferred to another part of the index. This has been done in the case of "Cameras,

Reflex," which are found under "Reflex Cameras" to the number of twenty-one entries. The reader will thus see that the guiding principle to the index is that of subject. The essential descriptive feature of an article or paragraph, such as "Plate," "Camera," "Lens," or "Developer," is that under which it should be looked for in the index. Thus "Mawson Gladiator Plates" will be found under "Plates," not under "Mawson." In short, the entries in all cases fine down from the general to the particular.

\* \* \*

#### **A Camera Club in the West End.**

We understand that Mr. Reginald Craigie has been interesting himself in the formation of another camera club, and if sufficient support is forthcoming suitable premises in the West End will be secured, which will comprise smoking-room, studio, enlarging-room, arc-light printing-room, workroom, and several dark-rooms. The use of these will be free to members, with the exception of the studio, for which there may possibly be a trifling charge. No liability will attach to membership beyond the annual subscription, which will be three guineas, two guineas, and one guinea for town, country, and foreign members respectively. No entrance fee for original members. An influential committee is being formed. Those who are prepared to support such a scheme and to become members should communicate at once with Mr. Reginald Craigie, Blenheim Club, King Street, St. James's, S.W.

#### **PHOTOGRAPHERS AND ASSISTANTS' AGREEMENTS.**

THE question of radius agreements by which employees are bound under certain restrictions has once more come into prominence. In our last issue is a letter of a correspondent, who signs himself "Observer," calling attention to an article in the "Daily News" of some few weeks back. Again, in this week's issue of our contemporary, the "Pharmaceutical Journal," there is another on the same topic, in which complaint is made that employees are often prohibited from taking over or starting a business, or from entering the service of another employer in the same line of business within a certain defined radius. The article in the last-named journal has naturally reference mainly to chemists and druggists, but assistants who have the management of branch establishments are much in the same position as are operators and managers of branch photographic establishments. It often happens, in both cases, that after a couple of years or so they become better known to the customers than are the principals themselves, for the latter may not even be known at all in the business. It is for this reason that restrictive agreements have been long in vogue. Such agreements in various trades have in the past led to much litigation in the law courts, but in recent years little has been heard of these actions.

Radius agreements—very general with reference to the sale of photographic businesses—are usually to the effect that the seller will not open, carry on, or be connected with any other in the same or similar line within a stipulated distance, so it will be seen that the conditions in the sale of a business or the engagement of an operator are pretty much on all fours with each other. What has really brought this subject into some little prominence just now is a case which was before the courts a little while ago:—A young man was engaged as a junior reporter on a provincial newspaper, and he signed an agreement at the time to the effect that he would not work for any other journal in the district. However, he left this employment and entered the service of a rival journal; whereupon an action was entered against him for breach of contract, and the plaintiffs gained the day. This judgment was

appealed against, with the result that it was reversed, but on a legal technicality only. The agreement was declared not binding, inasmuch as the defendant was not of full age at the time he became a party to it. Had it not been for that there is a great probability that it would have held good.

It goes without saying that the crux of the radius agreement question lies in the fact of the manager of a branch establishment becoming, as he is bound to do, so identified with the business that in the event of his setting up in business for himself or going to another studio, he could draw many customers after him. It is with a view to meeting such cases as this that many photographers, when they engage an operator or manager, make it a condition that in the event of his leaving he shall not, within a given time—say, two years—commence business for himself or enter into partnership with, or the service of, another photographer within a certain radius under a certain penalty. In this way the employer is protected and no injury is done to the employee; he has signed the agreement and knows full well the conditions under which he takes the appointment.

It is argued by some that these radius conditions are arbitrary and are an undue restriction of trade by preventing competition, which is against public policy. Such agreements, however, are but fair, supposing they are framed in a reasonable way, though frequently they are not. We have at times had sent for our opinion thereon copies of agreements between photographic employers and employees which have been altogether one-sided, and for that reason would have been held invalid if contested in a court of law. One which we call to mind was to the effect that the operator, on leaving, was not to carry on business, or be employed by another photographer in three adjoining counties—no time limit being mentioned. It need scarcely be mentioned that such a contract as this was unreasonable, and therefore invalid, as it was unquestionably an undue restriction of trade.

Another case in no way connected with photography comes to our mind. Yet we may comment upon it as being of interest to photographers as well as to assistants. A firm of drapers and house furnishers sought an injunction against a former manager to restrain him from carrying on business with his wife, he having signed an agreement not to enter the service of any person or firm, or to enter any business in opposition to his late employers within a radius of ten miles of Lancaster, and in the event of his doing so he agreed to forfeit a year's salary (£120). He was then carrying on business with his wife as a draper within a couple of hundred yards from his late employers' shop. The defence to the action was that the agreement was void because it was too wide, being an undue restriction of trade and against public policy. The Court held that the covenant was greater than was necessary to protect the plaintiffs' interests, and that the agreement, therefore, was invalid and could not be enforced. We merely refer to this case to show that an agreement may be so wide that it may defeat the end that an employer has in view.

Many agreements are drawn out by photographic employers themselves, and they often make them so unreasonable that for this very reason very many of them are not worth the paper they are written upon, if contested, but in some cases they may serve to intimidate the employee for the time being against taking employment with a competing photographer. And that is an evil which we would wish to see dispersed from the photographic profession, to which end we shall be glad to hear the views of readers of both classes, and to comment upon such suitable cases as they may put before us.

## AN EXPERIMENTAL STUDY OF THE LIPPMANN COLOUR PHOTOGRAPH.

### III.

#### The Production of White.

On Lippmann's theory, white is produced by reflection from particles of silver thickly and irregularly distributed through the film. Regularly spaced laminae would be entirely absent. Such a deposit would be formed in a perfectly isochromatic emulsion provided the wave-lengths of the acting light varied between wide limits and the individual silver grains were of appreciable size. If, on the other hand, the acting light varied between rather narrow wave-lengths limits, as from red to blue, the size of the silver grains being negligibly small in comparison to the shortest wave-length, a rapidly damped standing vibration of wave-length equal to the mean incident wave-length would result. In Fig. 3 is given the standing wave form due to light from red to blue, in Fig. 4 the form when the incident light is from infra-red to ultra-violet and the silver grain coarse.

Lippmann pictures have been made exhibiting beautiful whites, yet general difficulty seems to have been experienced. This is partly due probably to the difficulty, with present known sensitisers, of securing isochromatism between wide limits. Several other theories have been proposed and other experimental methods tried to produce white. Lehmann concludes that the greenish appearance sometimes found in whites on short exposure is due to laminae formed in the manner described above. He corrects this by using a screen with three maxima of transmission—red, green and blue. On short exposure whites will be reproduced as a mixture of these three colours. A serious objection to this method is that colours falling in the minima of transmission will be poorly reproduced.

Fig. 3.

Standing waves formed by white light from red to blue, as recorded in fine-grain emulsions.

Fig. 4.

Standing waves formed by white light, from infra-red to ultra-violet, as recorded by coarse-grained emulsions.

Cajal from his work concludes that white is due to the formation of a mirror-like surface on the film, and that this can be produced only by the use of amidol as an intensifier. The mirror-like appearance presented by the high-lights of Lippmann pictures readily lends itself to the idea that the surface is a silver mirror. That that is possible only when the picture is intensified with amidol is, however, a conclusion unsupported by other experimenters and contradicted by the undoubted production of white by Neuhaus and others who did not use this intensifier.

The possible modes of production of white are therefore three. First, by a general diffuse deposit in an isochromatic emulsion. Second, by forming laminae corresponding to red, green and blue. Third, by producing a mirror surface. The second method was not tried in the present investigation, as being obviously a compromise.

Attention was therefore turned to producing an isochromatic emulsion by combinations of colour screens and sensitisers. Numerous sensitisers were tried; of these much the best was Isocol, in that it imparts a sensitiveness free from gaps or maxima. The sensitiveness given by it extends from deep red to blue and violet, gradually increasing toward the latter. Absorbing solutions of wool black, cobalt sulphocyanide and iron sulphocyanide reduced the action in blue, green, and yellow to that in deep red and gave very satisfactory isochromatic action from red to ultra-violet.

Plates similar to those used in the study of monochromatic colours were prepared and exposed to white, at first with disappointing results. Not only was there practically no light reflected from the

partially exposed parts, but the mirror-like high-lights were absolutely black. By intensification with amidol the plates could be made to reflect considerable light. This led to the question whether the intensifier did not merely increase the size of the grain, and whether this might not be done in the emulsion. That the grain was too fine to give whites by diffuse reflection was also indicated by the fact that a fogged plate appeared black and not white by reflection.

A series of emulsions were then made up containing increasing quantities of silver. These were exposed without the mercury mirror and the character of the deposit examined. It was at once apparent that while a very fine grain reflected diffusely very little light indeed, a coarser grain gave a strong white reflection which in the high-lights became mirror-like. The brightest whites were given by an emulsion containing four times the silver content of that used for pure colour work, or twice that used by Lippmann and others. This emulsion used with the mercury mirror gave perfect white. The theory that diffusely distributed reflecting particles formed in an isochromatic emulsion produce white is therefore supported.

As to the theory of Cajal that white is given only by a mirror-

Fig. 11.

like surface, this was not supported by the results here obtained. The whites were quite perfect in the partially exposed parts. In fact, it is the writer's opinion that the formation of the mirror appearance indicates rather the point where the white ceases to be good. A very slight exposure beyond this point, giving the clear yellow by transmission, results in the white becoming black. Everything is in agreement with the view before advanced that the mirror appearance is due to the merging together of the separate particles with resulting loss in reflecting power. White will be given only so long as the particles are separate, being similar therefore to the white given by powdered glass or other substance transparent in the fused condition.

Since the range of sensitiveness of the emulsion is at best rather limited, and since the grain must be kept small enough to render all colours ordinarily met with, it would not be surprising if some tendency should exist to form laminae corresponding to the mean wave-length—i.e., green. No appearance of green on under-exposure of whites was observed. Before mounting the prism the film had an orange tinge which turned to greenish on increasing the angle of incidence. The explanation of this is given by Fig. 4. Although complete laminae corresponding to green light are not formed the deposit of silver

increases in density from the surface to the point where the first lamina would form. Rapid damping prevents the formation of more surfaces. There is therefore a slight gap between the surface and the heavy deposit, forming a single thin film. On mounting the prism the upper surface is virtually destroyed. The orange colour is what we should expect from Wiener's explanation of the shift of all colours towards red as long as the surface reflection is active.

Sections supported these conclusions. Laminae were absent: in their place a structureless deposit, increasing in strength toward the surface, reaching a maximum a short distance from it, the maximum corresponding to the distance in of the first lamina due to green light, as near as could be determined. This appearance is shown in Figure 11.

### Photography of Natural Objects.

To photograph natural objects, conditions must be such as to give whites and colours of small spectral purity. This is secured by using a fairly coarse grained isochromatic emulsion developed with a developer giving a transparent highly reflecting deposit.

For experiments in this direction a number of different emulsions and modes of preparation were tried. Good results were obtained with very coarse grained ones, but experience showed the proportions of silver bromide and gelatine in most general use to be probably the most satisfactory. Little choice exists between the several modes of preparation published. The silver nitrate may be digested with part of the gelatine, dissolved in water and added, before mixing, to one part of the gelatine; dissolved in water and added to the gelatine containing the potassium bromide; or added in dry powdered form to the latter. The quantity of silver bromide is double that found best for monochromatic light reproduction.

To secure isochromatism, Isocol as a sensitiser, with the absorbing solutions above given, or, as the sensitiveness imparted by Isocol is very fugitive, a more permanent combination of pinacyanol and pinavdol, with a screen of wool black, was found to answer fairly well.

The only point in the manipulation not yet described is the choice of film thickness. The standing wave structure being shallow great thickness is no object. Speed, too, is gained by small depth. The thinnest film is obtained by flowing the warm emulsion on and off glass plates warmed to the same temperature. This gives a thickness of about 1.400 mm., on which most colours reproduce satisfactorily, as far as the eye can tell. The resolving power is small, of course, and some anomalous results are to be expected. Purple is about the only colour of any complexity often met with, and the film should be thick enough to resolve its two maxima well. The most satisfactory thicknesses was obtained by flowing the emulsion on and off glass plates at room temperature, about 1.200 mm. Exposures with  $f/5.6$  on sunlit objects ranged from  $1\frac{1}{2}$  to 5 minutes, according to sensitisers, etc.

With emulsions made up and used in this way good colour rendering was obtained. The sum total of the results on photographing natural objects has been to vindicate the procedure indicated by theory and carried out by Lippmann. The deviations from that procedure by Lehmann and Cajal seem unnecessary to secure successful results.

The difficulties noted by all workers with the process as applied to photographing natural objects were found to be very real. They are, in brief, the great dependence of success on correct exposure and development. Very slight deviations will make the colours either weak or diluted with white. This is due to the laminae being few and close to the surface. With pure colours a certain amount of dlogging up affects but a small part of all the laminae; in diluted colours, practically all. A larger proportion (twice as much) of bromide in the developer than was used for pure colours was found to materially help the brilliancy of these colours. A larger percentage of failures is to be expected in any process of colour photography than with black and white, since the eye is more sensitive to errors of treatment where colour occurs. The sensitiveness of the Lippmann process to slight deviations from correct conditions is, however, much greater than the three-colour method, and good results only come from repeated patient trials. When obtained they are extremely dependent on correct viewing conditions to appear to any advantage. The colours, being formed for the most part by two or three laminae, backed up by a diffuse deposit, great care must be

taken to exclude all light, except that coming in the direction to be regularly reflected by the laminae. Light from other directions is not sent to the eye by the laminae, but is by the diffuse deposit, causing a drowning out of the colours with white light. By making the film excessively thin so that the laminae are formed, but not the deposit behind, the colours are more brilliant and less affected by conditions of illumination. Colours of any complexity, such as purple, however, suffer.

### A Substitute for the Mercury Mirror.

One of the obstacles to wide use of the Lippmann process is the necessity for a mercury mirror. Each plate-holder must be arranged as a tank, into which, before exposure, mercury must be flowed. Several attempts have been made to obtain substitutes for the mercury. Krone<sup>14</sup> dispensed with it altogether, relying on the gelatine-air reflection, but the colours are then dull and unsatisfactory. Lehmann has flowed the emulsion on a collodion coated polished metal plate. After exposure composite film could be stripped and placed on a glass plate. Pure colours, spectra, etc., can be so reproduced, but those whose lamina system is close to the surface cannot, since that space is occupied by the collodion. Placing a silver mirror in close contact with the gelatine has the same objection.

The writer has recently discovered a substitute for the mercury mirror, of a form which permits the plates to be handled and used precisely as ordinary dry plates.

The procedure is as follows:—A glass plate is heavily silvered and then flowed with a thick solution of celluloid in amyl-acetate. When this varnish is dry, the plate is placed under water; this slowly works under the coating of celluloid, lifting it from the glass, and bringing with it the silver. This flexible silver mirror is immediately laid, silver surface down, on a wet Lippmann plate, and allowed to dry there, a necessarily somewhat slow process. When dry the gelatine film has the silver surface in optical contact with it. The plate may then be exposed at any time in an ordinary plate-holder. After exposure the celluloid film is stripped from the gelatine, taking with it most of the silver, the plate developed, and after thorough washing the remains of the silver removed with a tuft of wet cotton.

This substitute works perfectly for all types of colours, and, except in the laboratory, where a convenient dark-room makes the use of the mercury mirror simple, facilitates the practical working of the process. Especially would it do so for the photographer who buys his plates ready made. In that case the only difference between ordinary and colour photography would be the longer exposure in the latter case, and the necessary mounting of a prism on the picture, and, of course, the impossibility of copying.

A difficulty which has proved rather troublesome is that some of the best sensitisers are apt to lose their effect during the slow drying. Erythrosin acts perfectly; pinacyanol and pinaverdol are apt to fail. This can probably be overcome, either by different choice of sensitisers, by so treating these that slow drying does not harm, or perhaps by finding some more porous substance than celluloid which, acting the same in other respects, will permit quick drying. Collodion has been tried, but has not been found to strip off the gelatine well.

### Three-Colour Interference Pictures.

The capacity of the Lippmann film to reproduce pure spectrum colours easily and with certainty adapts it for an application to the three-colour process, published by the writer some time ago.<sup>15</sup> In the synthesis of the properly taken records of the three-colour sensations, spectrally pure red, green and blue light are called for. The Lippmann film furnishes an unequalled means for securing these.

The method used was to place before the plate an opaque-line screen, having opaque spaces twice the width of the transparent. The three positive colour records were projected one after the other with their appropriate coloured lights, the line screen being moved each time the width of a clear space. The result was similar to the Joly picture, consisting of alternating lines of red, green and blue.

In the first pictures so made the coloured lights were obtained from sunlight by a monochromatic illuminator, but satisfactory purity and shortness of exposure were not secured. In experiments since carried

<sup>14</sup> "Darstellung der natürlichen Farben durch Photographie, 1894."

<sup>15</sup> "Physical Review," January, 1907, p. 103.

out the line screen was removed from contact with the plate, as this necessitated a narrow source of light, and placed in contact with the three-colour positive, an image of the screen and positive being formed by a Planar lens of fine defining power. For light sources the cadmium red line ( $\lambda$  6439), the magnesium green ( $\lambda$  5170), and the lithium blue ( $\lambda$  4602) were found most available, obtained in the manner described in a following section.

The three-colour interference pictures so made are of great brilliancy and beauty, especially if the hydroquinone development and bleaching are used, when the component colours are of practically ideal purity. Quite long exposures are necessary, amounting under the best conditions to a total of fifteen or twenty minutes. This time can probably be materially reduced. The pictures are, however, far more easy and certain, besides being more brilliant, than the regular Lippmann picture. They constitute an excellent means of carrying out the three-colour principle, and have the interesting property of owing their colour to the direct action of light and not to pigments or coloured glasses as do the other three-colour schemes. They can besides be duplicated indefinitely.

### Sensitisers.

During the progress of the work various colour sensitisers were used, depending on the portion of the spectrum photographed. The list included erythrosin, cyanine, pinacyanol, pinaverdol, pinachrome, isocol, homocol, and dicyanine. For bathing 1-100,000th solutions in water were used, without ammonia; in the emulsion about 1 cc. of a 1:1,000 alcoholic solution to 100 cc. of emulsion. Some observations of their behaviour with these very slow emulsions are of interest.

In general it was found that bathed plates acted more cleanly and brilliantly, two sensitisers, isocol and homocol, acting very poorly in the emulsion. Ammonia was not used, as it has a tendency to make the plates ripen, with consequent great increase in the grain. Bathed plates were, however, unsuitable for a large part of the work, since the sensitising action extends only a short distance into the film, even with long bathing. Figure 10 shows a section of a plate bathed fifteen minutes in a 1-100,000th solution of homocol. (Page 965, issue December 18.)

For green all of the sensitisers are good except cyanine, dicyanine, and pinacyanol. For the red pinacyanol is far and away the best, the action of cyanine not extending far enough down, and that of dicyanine being too feeble. The great difficulty has been to sensitise for the light blue. On ordinary plates there is apt with many sensitisers to be a minimum in the blue-green near  $\lambda$  5000. On these slow plates this gap is in the blue. This is owing to the natural sensitiveness of the plates only extending to the violet, while with fast plates it goes down to the blue. The descending curve of green sensitiveness imparted, say, by erythrosin meets the descending curve of the emulsion's own sensitiveness, in the one case in the blue, in the other in the blue-green. This was verified by greatly reducing the amount of sensitiser, when the weak blue-sensitiveness was stronger than the imparted sensitiveness in the blue-green. This behaviour of the plates makes sensitiser combinations, such as pinacyanol, homocol, and pinaverdol,<sup>16</sup> which fill the blue-green in ordinary plates, inefficient here. A blue sensitiser, not needed for fast plates, is really required with the Lippmann plates. Isocol was the only sensitiser found which gave a sensitiveness free from gaps.<sup>17</sup>

As to the keeping qualities of the sensitised plates, it was found that the erythrosin-cyanine or erythrosin-pinacyanol emulsion plates kept well, at least for a week or two. Bathed plates lost their sensitiveness quite rapidly; isocol bathed plates in four or five hours, rendering them useful only for quickly carried out experiments. Pinaverdol in the emulsion in one case lost its action in four days. Pinacyanol and pinaverdol emulsions, which dried slowly, as those prepared for use with the silver-celluloid mirror, sometimes showed complete loss of colour sensitiveness.

### Sources of Monochromatic Light.

In the study of monochromatic light reproduction and in making three-colour interference pictures difficulty was experienced in finding suitable monochromatic sources. As the plates are very slow, and large surfaces were illuminated, sources capable of giving a large quantity of light for a long period were essential. Many

ordinarily used sources were useless, either because of their small intrinsic brilliancy, or because of their too short life. The spark, the vacuum tube, the flame, arcs between easily melted metals, were among these. Another requisite was that the line used should not be so near other lines as to render its separation impossible by means of absorbing screens; resolution by means of a prism causing too much loss of light.

The following list of the most satisfactory sources found is given as of possible use in other lines of work where great intensity for a long period is required. It is by no means complete, since search was stopped when a satisfactory one for any colour was found. Where obtainable, the best sources are undoubtedly the Hereaus fused quartz lamps and the mercury vacuum arc. The open arcs here tested are, as a rule, more brilliant and are easily manipulated. Carbon was used uniformly as negative electrode.

*Red.*—Lithium 6708. Lithium sulphate in cored carbon.

Cadmium 6439. Cadmium ordinarily burns with dense brown fumes which form a cake of brown oxide around the rapidly melting electrode. This may be avoided by melting the cadmium into a copper tube. The copper and cadmium lines appear together, but the red cadmium line is distant from the copper lines. A current of not more than four amperes is best.

*Orange.*—Lithium 6103. Lithium sulphate in cored carbon.

*Yellow.*—Sodium 5893. Sodium chloride in cored carbon.

*Green.*—Thallium 5360. Metallic thallium in cored carbon.

Magnesium 5162, 5172, and 5167. Magnesium powder in cored carbon.

Silver 5460 and 5209. Silver, which in rods melts in a few seconds, burns steadily and brilliantly if a thick wire is placed in a cored carbon. Wire of 2 mm. diameter in a carbon of 10 mm. diameter gave excellent results.

Cadmium 5085, obtained from an alloy of tin and cadmium in a cored carbon, one part by weight of cadmium to six of tin.

*Blue.*—Lithium 4602. Lithium sulphate in cored carbon.

Solutions of various aniline dyes separated most of these clearly. Copper chloride was found useful when either end of the spectrum was to be absorbed. With increasing concentration its absorption moves in, maintaining constantly a sharp boundary. Care must be taken that the temperature of the solution does not rise while in use, as this causes widening of the absorption.

### Relative Position of Reproduced with Reference to Incident Wave-Length.

Owing to the partial solubility of the gelatine, and perhaps the washing out of unaffected silver bromide, the films show a general tendency to shrink in development and washing. This causes the colours to shift toward blue. This tendency is much more marked when the plates are fixed with "hypo." In most of the work fixing was dispensed with, Lehmann having found the pictures to keep perfectly without. This shift is much more marked with pure colours than with mixed, the interlaminary spaces being freer of deposit. This is well shown by photographing a continuous spectrum, using a rather wide slit, beside a line spectrum; the lines are reproduced as noticeably of shorter wave-length tint. If the slit is then closed up to extreme narrowness and exposure made, the spectrum colours agree in tint with the monochromatic lines.

Bleaching with mercuric chloride on the other hand swells the film; the two processes of fixing and bleaching therefore tend to neutralise each other.

In working with very thick film, a spurious "Doppler effect" frequently occurs. The surface portions of the film wash away more than the deeper, so that a diffuse band of light appears on the blue side of the sharp line.

### Characteristic Curve.

In the photographic plate the density by transmission varies nearly directly with the time of exposure. This is because the deposit of silver is in logarithmic relation to the time of exposure, and the increase of opacity of an absorbing medium also follows such a law. When the deposit is viewed by reflection this relationship between exposure and intensity does not hold, the relation becomes logarithmic instead of linear. The exact relationship is complicated by absorption, which tends to hasten the "saturation point." A further complication arises in the Lippmann process with very short exposures owing to the necessity for the reflecting particles to have a certain size and a certain closeness to each other to

<sup>16</sup> R. J. Wallace, "Astrophysical Journal," December, 1907.

<sup>17</sup> The sensitisers used were of the following makes or sources:—Pinacyanol, pinaverdol, pinachrome, dicyanine from Meister Lucius and Brünig; isocol, homocol from the Bayer Co.; cyanine from Eimer & Amerd, New York; erythrosin from F. A. Reichardt, New York.

form a regularly reflecting surface. This was observed in a plate one-half of which was exposed behind a coarse opaque grating with lines covering two-thirds of the surface. The part behind the grating was exposed to nearly full exposure, the part not covered exposed until, when held at arm's length (where the lines were no longer visible), the two parts appeared of exactly the same density. By reflection the portion only partly covered by the full exposure was much more brilliant than the portion completely covered by the shorter exposure.

These several effects tend to shorten the scale of gradation of the plate, unfortunately, because the eye is more sensitive to this defect in coloured than monochromatic pictures.

### Different Rates of Development for Different Colours.

In developing three-colour negatives where all three images are on one plate it has been observed that the three images develop at different rates, although the exposures and the final densities are correctly proportioned. The Lippmann film exhibits the effect clearly. In making three-colour interference pictures the colours were found to depend considerably on the time of development. With short development the green and blue predominated, with longer the red became stronger, the final picture showing, however, the relative exposures not too long for blue and green. Trouble from this effect was easily avoided by keeping the time of development constant and regulating the exposures for that development.

### Summary of Results and Conclusions.

*Reproduction of Monochromatic Light.*—A smaller amount of silver bromide than usually employed gives purer reflected light from the Lippmann film.

Increase in thickness beyond about 1.200 mm. causes no corresponding increase of purity so long as pyrogallie acid development is used.

The standing waves are formed throughout the thickness of the film; the non-formation of laminae is due to the surface action of the developer.

Other developers, such as hydroquinone, develop evenly through the film. By bleaching the deposit formed by their use films are obtained giving purer reflected colours than heretofore obtained and increasing in resolving power with thickness.

*Mixed Colours.*—Films developed with pyrogallie acid have small capacity for rendering complex structure, but luminosity values are well preserved if the grain is not too fine or exposure too long.

With hydroquinone and bleaching, complex radiations are produced with a fidelity dependent only on the practically attainable thickness of film. This resolving power is at the cost of luminosity.

*White.*—White is produced by the action of white light on fairly coarse-grained rigidly isochromatic emulsions.

*Natural Objects.*—The colours of natural objects are well reproduced by emulsions suitable for giving whites and mixed colours, i.e., of somewhat coarser grain than is best for pure colours.

Pictures of natural objects are much more difficult to obtain than those of pure colours, because of the shallowness of the standing wave structure.

*Substitute for the mercury mirror.*—A means has been found of affixing a silver reflecting surface in optical contact with the film, enabling the mercury mirror to be dispensed with.

*Three colour interference pictures.*—The Lippmann film, by reason of its capacity for reproducing pure colours, is well adapted to application to three colour photography.

In conclusion, I wish to acknowledge my indebtedness to my father, Mr. Frederick E. Ives, whose lifelong experience with photographic processes has always been freely placed at my service. I also wish to thank Professor J. S. Ames for the kindly interest he has shown in the progress of the work.

HERBERT E. IVES.

*THE PHOTO-SECESSION.*—An exhibition of photographs by the members of the Photo-Seceession has been held at the Little Gallery of the Photo-Seceession, 291, Fifth Avenue (between Thirtieth and Thirty-first Streets), New York, from December 8 to December 30.

### A MADMAN UPON THE FELLOWSHIP OF THE ROYAL PHOTOGRAPHIC SOCIETY.

THE Fellowship of the Royal Photographic Society is a matter which has caused much heartburning. There are some who think that the four coveted letters will cease to be a distinction if they are awarded on terms too easy. These worthies consider that a thorough examination should be the ordeal by which candidates for the honour should stand or fall, and that even this should be supplemented by a scholarly thesis implying original research. There are reasons for believing that candidates for the Fellowship have allowed the uncertainty of election so completely to oppress their minds as to impair their powers of connected thought; at least, that seems to be the only explanation of the existence of a document, the writer of which, it is lamentable to observe, is in a state of utter mental aberration. By what motives he has been inspired to string together a catechism, which is evidently advanced as a model examination paper, we will not seek to divine, yet it would seem to be our duty to make some extracts from the manuscript which bears these painful evidences of a wandering mind:—

Q.: What do you understand by a "convertible Cooke lens"?

A.: A cook who lends herself to general housework also, when required to do so.

Q.: Describe the "Primo-plane" variety.

A.: That is obviously one who stands in the first rank of unprepossessingness.

Q.: What are Tripods?

A.: Odds and ends from the Tripe-shop.

Q.: How is the term "Uto" applied?

A.: It is applied to paper used presumably for corn-plasters.

Q.: What are your views as to professional practice at sea-side resorts?

A.: I am of opinion that "stripping," "exposure" and the "combined bath" should be prohibited, and that the use of a "hiding-tent" should be made compulsory.

Q.: How would you prevent "frilling"?

A.: By insisting upon the utmost plainness and decorum in the attire of females; especially such as are over-developed.

Q.: What do you know of photography as practised on "The Turf"?

A.: "Dry mounting" is unknown; but "backing" is universal and does not slow the horses. On the Turf, the "plate" is usually the objective, though "cups" and "steaks" are used for the purpose occasionally.

Q.: Explain the terms "Una," "Rex," "Adon," "Tella."

A.: Una is a lady with a swing-back caused by the oscillations of Rex, the king of beasts, upon whom she rides. Adon refers to the clothes she 'ad on once. Tella of her impropriety is what nobody dare do.

Q.: What do you recommend as a rest-cure for over-worked photographers?

A.: Lying in fallowfields, listening to the sanger-shepherds and emulating their imbibition process.

Q.: What is "Falloroll"?

A.: I should take it to be the words of a chorus carolled by counter-men when sales are effected.

Q.: What does the trade name "Tress" signify?

A.: Fittingly enough it is the name of a 'air-brush pump.

Q.: What do you recommend as a remedy for congestion in the case of a person "bolting silk"?

A.: "Flash powders" until the patient is relieved.

It will be seen that the poor demented has already got right away from a semblance of technicality; but he goes further yet:—

Q.: Who are your favourite heroes in history?

A.: Wellington and Ward Beecher.

Q.: What are your favourite retreats?

A.: "Barnet" and "Ilford."

Q.: What are your politics?

A.: "Imperial."

Q.: State your favourite brands.

A.: "Red Seal" and "Black and White."

Q.: What is your opinion of the recent weather?

A.: Wrotten and Rainright!

Q.: How would you describe the foregoing paper of questions?  
A.: A Zschokke.

His son was much astonished at finding the following table written upon a leaf of his summing book:—

40,000,000 grains=1 autochrome.  
12 autochromes=1 satisfactory transparency.  
2 satisfactory transparencies=1 unscrupulous enthusiast.  
6 unscrupulous enthusiasts=1 exhibition.  
2 exhibitions=many astounding critiques.  
Many astounding critiques=1 hollow reputation.

It is remarkable how sometimes a disordered mind may stumble upon the truth. In the matter of theses he had some noteworthy ideas, as may be seen from an ideal syllabus prepared by him. We cannot refrain from quoting:—

"Mucilage in Art," by J. C. S. Gummery.  
"The Improvement of the Negative," by T. Born Faker.  
"British Vermin," by Bugless English.  
"Stagnation in the Brine Tub," by T. E. Freshwater. Demonstration by Drinkwater Butt.  
"Oil, Toil, and Pignoil," by John H. Smear.  
"The Behaviour of Children Before the Camera," by E. T. Scolding, assisted by Rev. F. C. Damberty, MA!  
"How to be Happy though Domestic," by Be Gay Milk-in-son, supported by Ernest Marriage.  
"Photographic Hardware," by F. Mardun Tincan.  
"No-cap Exposure," by Dr. S.E.E.K. Sneeze.  
"Heroism in Hand-camera Work," by F. J. Mal de Mer.  
"Our Wayside Inns," by Chas. H. Soak-den.  
"The Use of the Handkerchief in Bromoil Printing," by C. Well-worne Wiper.  
"Sheep's Blood as a Colouring Agent," by E. Sang-er Shepherd.  
"Photography in Winter," by H. Snowed-on Sward.

The fine catholicity of taste shown by these titles proves how fine an intellect has here fallen into ruin.

#### TONING AND VARNISHING OF BROMIDE PRINTS.

A FORMULA for the toning of bromide prints, which, in the newly-issued volume of Herr Fritz Loescher, reviewed on another page, is recommended for giving much purer whites than the ordinary uranium formula, is as follows. Four solutions are prepared:—

A. Lead nitrate .....	1 gm.
Potass ferricyanide .....	3 gms.
Water (distilled) .....	50 ccs.
B. Uranium nitrate .....	1 gm.
Water .....	100 ccs.
C. Citric acid .....	10 gms.
Water .....	50 ccs.
D. Ammonium chloride .....	1 gm.
Water .....	100 ccs.

To form the toning solution the following proportions are mixed:—

A .....	25 ccs.
B .....	100 ccs.
C .....	100 ccs.
D .....	20 ccs.

The bath gives red chalk tones; for brown tones, the D solution is omitted, and the proportions given above taken of the first three. A further advantage of this formula is that the prints do not lose intensity on washing, and this process can therefore be thoroughly carried out.

The use of varnish and encaustic pastes for bromide prints has the advantage of imparting to the finished print much of the rich luminous appearance which it possesses in the wet state, and, moreover, in the case of a print toned by a process which is not above suspicion, it undoubtedly prolongs the life of the print. Herr Loescher in his book recommends the use of a commercial encaustic paste; in this country he would doubtless have pointed to the "Lustralene," of the Vanguard Company, which is a standard article of this kind. He further advises the use of a shellac varnish, applied with an atomiser, but not to the extent to give the print a matt surface. A further suitable varnish is a shellac solution, containing copaiva

balsam. A fairly thick solution of white shellac is prepared, a little copaiva balsam added, and the mixture largely diluted with absolute alcohol before being applied to the print with a broad camel-hair brush.

Especially for the treatment of mounted prints the so-called "Zapon-lack," sold specially for the purpose by the Leto Photo-Materials Company, may be advised, since it does not injure the mount in the slightest, and may be repeatedly applied.

#### THE NORTHERN EXHIBITION.

THE following is the programme of lectures to be delivered at the forthcoming Northern Photographic Exhibition to be held in the Manchester City Art Gallery from January 7 to 27:—January 7, "Snow and Ice Scenery in Switzerland," C. Thurstan Holland; January 8, "In Search of Sunlight," E. Rimbault Dibdin; January 9, "Afar in the Fatherland," W. L. F. Wastell; January 11, "Japan and the Japanese," Dr. Murray Cairns; January 12, "The Foot Hills of the Eastern Alps," J. Dudley Johnston; January 13, "Leaves from Nature's Book," J. W. Wade; January 14, "Chetham Hospital: Its Founder and Site," J. J. Phelps; January 15, "Picturesqueness of the Commonplace," Rev. Henry W. Dick; January 16, "The Camera and the Sea," F. J. Mortimer; January 18, "The River Mersey from the Moors to the Sea," Dr. John W. Ellis; January 19, "Dutch Pictures," Arthur Marshall; January 20, "Gorges of the River Ardèche," G. E. Thompson; January 21, "Rothenburg and its Festival Play," James Shaw; January 22, "Sunshine and Snow in the Bernese Oberland," S. L. Coulthurst; January 23, "The Thames Valley" (illustrated with Autochrome slides), J. McIntosh; January 25, "Some Picturesque Midland and Cotswold Villages," W. A. Clark; January 26, "Land of William Tell," F. W. Parrott; January 27, "Westminster Abbey," S. G. Kimber.

## Exhibitions.

#### THE MARION PRIZE COMPETITION.

The prize prints and others (to a number in all of 83) selected from the recent competition organised by Messrs. Marion and Co., Ltd., are now on view at the offices of the "Amateur Photographer," Long Acre, where they form an extremely interesting exhibition. They do this, not so much from their pictorial quality, which is very variable even in the class assigned to work of this character, but from the particulars given in the catalogue as to the production of the prints and of the negatives from which they were made. The custom of naming the process in which a negative has been printed has so largely gone out of fashion at photographic exhibitions that the worker whose interest chiefly centres on the making of technically excellent prints of distinct quality necessarily finds little to interest him in even a leading show, since information as to ways and means is denied him. In the present instance, however, he has the advantage of learning the precise brand of paper employed, and the technical quality of almost every print on the walls is a testimony to the merits of the various manufactures of the firm of Marion in the way of printing papers and plates. It is easier, naturally, to speak of the former, and in particular we would signalise the effective use made of the various varieties of the "Marion" collodio-chloride paper and the "Marion" matt albumen; the latter is a brand of printing which deserves to be better known. Mr. Cavendish Morton's work is almost all in the collodio-bromide papers, and very fine technical printing it is, quite apart from its pictorial merits, on which it is not necessary for us to enlarge. The competition, it is satisfactory to find, has attracted a good few of the leading workers, but perhaps the best sign of the success which it has attained is the quantity of really good work by workers who are not regularly in the lists of exhibitors at the well-known shows. The award list has already been published in our pages, so that we need only now advise those who would spend half an hour inspecting a collection of fine prints and noting the methods of their production to pay a visit to 52, Long Acre.

## FORTHCOMING EXHIBITIONS

- December 30 to January 2.—Chelmsford Photographic Society. Sec., M. J. Morison, Savernake Lodge, Chelmsford.
- December, 1908, to January, 1909.—Kiew International Photographic. Sec., S. T. Horowitz, Technical Society, Kreshtchatik, 10, Kiew, Russia.
- 1909.
- January 1 to 9.—Scottish National Photographic Salon. Sec., Robert Telfer, 138, Glasgow Road, Wishaw.
- January 6 to 27.—Northern Photographic (Manchester). Sec., S. L. Coulthurst, Broad Oak Road, Worsley, Manchester.
- January 19 to 30.—Glasgow Southern Photographic Association. Entries close December 30, 1908. Sec., Robert Lindsay, 189, Allison Street, Glasgow, S.S.
- February 1 to 13.—Glasgow and West of Scotland Amateur Photographic Association. Entries close January 20. Sec., James M'Kissack, 68, West Regent Street, Glasgow.
- February 8 to 13.—St. Helen's Camera Club. Entries close January 27. Sec., A. G. Else, Duke Street, St. Helen's, Lancs.
- February 10 and 11.—Coves Camera Club. Entries close February 1. Sec., E. E. Vincent, 4, High Street, Coves.
- February 20 to March 20.—South London Photographic Society. Sec., H. Creighton Beckett, 44, Edith Road, Peckham, S.E.
- February 22 to March 6.—Birmingham Photographic Society. Entries close for abroad January 5, for England, February 12. Sec., Lewis Lloyd, Church Road, Moseley, Birmingham.
- March 17 to 20.—Nottingham Camera Club. Sec., E. L. Kent, 5, Radcliffe Mount, West Bridgford, Notts.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for patents have been received between December 7 and December 12:—

- DARK SLIDES.**—No. 26,443. Improvements in or relating to plate-holders or dark slides for photographic cameras. Herbert George Ponting, Chancery Lane Station Chambers, London.
- CAMERAS.**—No. 26,535. Improvements in photographic cameras. The Thornton-Pickard Manufacturing Company, Ltd., Arthur Gray Pickard, and Frank Slinger, 6, Bank Street, Manchester.
- CINEMATOGRAPHS.**—No. 26,677. Improvements in cinematographs or bioscopes. Percy Bennett, 259, High Street, Lincoln.
- DAYLIGHT DEVELOPMENT.**—No. 26,755. Improvements in and relating to the daylight development of photographic negatives on dry plates or cut films and appliances therefor. Frederick MacKenzie and George Wishart, 96, Buchanan Street, Glasgow.
- PLATES.**—No. 26,803. Improvements in or relating to photographic plates. Albert Thornley, 37, Chancery Lane, London.
- FILMS.**—No. 26,980. Improvements in films and film packs. John Owden O'Brien, 6, Bank Street, Manchester, for John Edward Thornton, United States.
- PRINTING APPARATUS.**—No. 27,047. Automatic apparatus for taking prints from photographic negatives, transparencies, and the like. Louis Brochery, 38, Chancery Lane, London.

### COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

**DRY MOUNTING.**—No. 13,253. 1908. This invention relates to an improved process for mounting photographs, etc., in a dry condition. It has already been proposed to mount by coating the back of the engraving or photograph with an adhesive made of resin or with a gutta-percha solution, or by placing a layer of paper coated on both sides with an adhesive made of resin between the photograph and the mount, adhesion being produced by heat and pressure.

According to the present invention a piece of paper or the like

is coated on both sides with a solution of gutta-percha or is passed through the latter. The liquid at first remains on the surface, which, when dry, appears to be covered with a thick white easily damaged coating. The paper is then exposed to the rays of heat on a hot plate or the like, whereby the liquid enters the pores of the paper, so that it has the appearance of being thin, transparent, and parchment-like, especially when strong thin tissue paper is used; the paper is then dried. In this condition it can be rolled up into rolls without any fear of it sticking together. By passing over a hot iron, between the above-mentioned rollers of a glazing machine, the adhesive soaked into the paper is slowly softened, so that it closely unites the paper, on the one hand, with the photograph or engraving, and, on the other hand, with the mount, without any of the adhesive exuding from the edges of the parts to be connected. The piece of paper soaked with gutta-percha prevents the mount, or any matter between the latter and the paper, from attacking the photograph (chemical decomposition), because the gutta-percha insulates to a certain extent. At the same time the solution of gutta-percha does not exclude the use of paste, dextrine, and the like with it, should such adhesives for any reason appear to be advantageous.

It is sometimes advantageous to coat the back of the photograph with the gutta-percha solution and then expose it to the heat radiated by a hot plate, so that the solution is caused to soak into the back of the photograph. The photograph is then caused to adhere to the mount by passing a hot iron over the same. Dr. Julius Neubronner, Cronberg, in Taunus, Germany.

**ENLARGING LANTERNS.**—No. 18,478. 1908. This invention relates to improvements in the condenser frame of lantern-enlarging apparatus, which receives the carrier with the negative to be enlarged. Hitherto this condenser frame has been made rigidly attached at right angles to the base with a slot to receive the negative carrier. This does not allow for any adjustment to correct any distortion on the negative owing to the camera having been tilted from the horizontal while the picture was being taken. This invention consists essentially in making the condenser frame of two parts, one of which is rigid and vertical to carry the condenser, and the other is pivoted or movable, so as to assume an inclination to the vertical

Fig. 1.

to receive the negative, the condenser carrier and stage or negative receiver being connected by a light-tight bellows or other flexible or sliding connection. Figs. 1, 2, and 3 show side elevation of lantern enlarging apparatus in three different forms.

The base 'A' is of the ordinary construction, with a lantern 'B' of the usual form, either for an oil, gas, or electric light, and a condenser hood 'C'. The condenser frame is constructed in two parts, a condenser carrier 'D' and a stage or negative receiver 'E'. The con-

condenser carrier is vertical and rigidly attached to the base A in the usual way, and to it the hood C is attached. The stage or negative receiver E is pivoted to swing out of the vertical and so place the negative relative to the plane of the lens to correct any fault or distortion therein that may occur owing to the camera not having been horizontal when the picture was taken; or, in other words, to place the negative in the same plane as that in which it was when the photograph was taken.

The stage or negative receiver E is connected to the condenser

Fig. 2.

carrier D by a light-tight bellows or other flexible connection F to prevent light escaping, or it may have a hood or a sliding connection for the same purpose.

The stage or negative receiver E may be pivoted or hinged at or near its centre to the condenser carrier D, the sides of either being shaped to allow of it swinging, as in Fig. 1, or it may be

Fig. 3.

pivoted at the top by a bracket e, as in Fig. 2, or it may be pivoted at the bottom, as in Fig. 3, or it may be otherwise arranged to fall to either side of a vertical axis.

A catch e<sup>1</sup> is provided to hold it in the desired position.

The front expanding bellows G are attached to the stage or negative receiver E. Thornton Pickard Manufacturing Company,

Ltd., of Altrincham, Cheshire; Arthur Gray Pickard; and Thomas Ripley Foxcroft.

**CINEMATOGRAH MECHANISM.**—No. 18,783. 1908. The invention relates to apparatus designed to take a series of consecutive pictures of objects in motion on a continuously moving film or other photographic surface. This is done, not, by moving the working lens, to compensate for the movement of the film (such movement of the objective, relative to the view, producing pictures blurred in outline and having the appearance of being out of focus), but the lens is fixed and the image formed by the lens is caused to follow the moving film by means of a movably mounted lens arranged between the objective and the film, which lens is moved to refract the rays forming the image in such a manner that the image during the total exposure remains on the same part of the film. It is preferred to use a cylindrical lens mounted in the exposure opening of an ordinary rotating circular shutter and provided with means whereby during exposure its axis of curvature is maintained at right angles to the line of movement of the film. Joseph Bianchi, 219, Church Street, Toronto, Canada.

**COIN-IN-SLOT PHOTOGRAPHIC CAMERA.**—No. 1,422. 1908. The object of the invention is to produce a coin-free apparatus always ready to produce photographs automatically simply on the introduction of a coin and in which the motive power is constant so that the various successive operations of photography, namely, the placing in position of the plate before the objective, the uncapping of this objective, the changing of the plate, its passage through the various baths and its drying may be carried out at a uniform speed whatever number of photographs have been already taken.

A further object is improved arrangements for effecting the different photographic operations, and particularly the final automatic drying of the plate.

Once the apparatus is installed, it works uninterruptedly without requiring any manual intervention other than that necessary for renewing the plates and the baths, when the latter are exhausted, and for turning by the use of the apparatus a crank one quarter of a revolution to obtain the delivery of the photograph; each such turning operation winds up the apparatus and automatically prepares it for the next operation of photographing an object.

All the movements of this apparatus are controlled by a main driving shaft which effects a complete revolution at each operation, and which produces by a series of suitable transmissions all the control necessary for the various operations to be accomplished. This principal shaft is actuated by any suitable driving mechanism, which is put in operation by the fall of a coin of definite value and is automatically stopped after a complete revolution of the main shaft.

In so-called automatic photographing machines as already known, the sensitised plates have been stocked previous to use in magazines and pushed therefrom by a slide so as to fall one by one into position behind the lens, the slide being operated by the shaft actuating the whole mechanism. After exposure the plate is allowed to fall into a wire cage or finger pivoted in a rotative frame which by travelling over a cam path, formed on the inner wall of a circular reservoir around the shaft, causes the cage to dip successively into the solutions contained in the compartments of the reservoir; the cam path being formed so that the cage at one period is so tilted that the finished photograph therein falls into a shoot for delivery. René François Frédéric Roupnel, 38, Rue de Fontenoy, Bourg la Reine (Seine), France.

The following complete specification, etc., is open to public inspection before acceptance under the Patents Act, 1901:—

**GLAZING PRINTS.**—Method and frame for drying gelatine-coated photographic proofs or other papers with the object of attaining a glazed effect by sticking them on polished surfaces. Ziegler.

## New Grade Dames.

**PANOS.**—No. 307,779. Cameras included in Class 8, photographic lenses, telescopes and binocular glasses, microscopes. Ross, Ltd., 3, North Side, Clapham Common, London, S.W., manufacturing opticians. November 9, 1908.

## Analecta.

*Extracts from our weekly and monthly contemporaries.*

### An Appliance for Fireside Developing.

In "Photography and Focus" for December 22, a writer describes a contrivance which he states "has been designed to facilitate fireside photography, and in the interests of domestic peace, and is known at home as his 'slop-catcher.'" This name exactly describes it and its purpose, for it is made to stand on the table when work is being done with solutions in dishes to prevent any of the liquids from getting on to the table-cloth and making a mess. The "slop-catcher" is in two parts—a frame to hold the dishes, bottles, measures, etc., that are in use, and a dish to catch what is upset from them. The frame measures 28 in. by 17 in., and is 2 in. high. It was made of half-inch teak by a carpenter in the town, and is dovetailed at the ends. He was told to avoid glue entirely as it would often be wet. A strut of the same material crosses it midway from side to side. The top is covered with a series of thin strips of the same wood. These are a little less than an inch and a half wide. They are a quarter of an inch apart, and are secured by screws. When this was made, the whole received three coats of white hard varnish. It has been in use for a couple of years, and is still sound, so the varnish may be supposed to be an effectual protection.

This frame fits inside a hollow tray, also made of teak. The tray is watertight, and the frame is made a fairly good fit in it, the height of the edges of the tray being arranged so that they come exactly on a level with the top of the strips on the frame. The outer angle of the sides of the tray are rounded off, as it was found that they hurt the wrists and elbows when work was being done on the apparatus.

## New Books.

"Vergrössern und Kopieren auf Bromsilber-Papier." By Fritz Loescher. Third edition, by Hans Loescher. Berlin: Gustav Schmidt. M2.50.

In this third edition of the book which forms Vol. 15 of the useful "library" series of treatises issued by the publishing house of Gustav Schmidt, the practice of bromide printing and enlarging is very fully treated. The preliminary chapters deal with apparatus for enlargement by day and artificial light, and with the optical principles on which they are based. These occupy more than one-half the volume. The development of bromide paper is somewhat shortly treated, toning processes rather more fully, though exception may be taken to the premier place given to the uranium method. Directions are given for copper and sulphide toning, but not for the thiomolybdate and thioannate modifications of the latter process, which have proved of great practical value in England. A useful final note concerns the use of varnish and encaustic paste for preserving bromides or enhancing their appearance.

"Der Oelfarben-Kopier Prozess." By C. Puyo. Translated by Dr. C. Stürenburg. Berlin: Gustav Schmidt. M1.80.

This volume (No. 24) of the "Photographische Bibliothek" is a translation of the French work by Commandant Puyo, a large portion of which we translated in our issue of August 30, 1907. Though practised in England with such energy, the oil process has been scarcely appreciated in Germany until quite recently. The journals have contained very little about it, and at the time of a visit which we paid to the Brothers Hofmeister less than six months ago, they had no practical acquaintance with the methods of Mr. Rawlins or Mr. Welborne Piper. Therefore Herr Schmidt is to be congratulated on issuing the first detailed description of the practice of the accomplished French workers.

"THE BRITISH ASTRONOMICAL WEATHER ALMANAC, 1909."—This publication, compiled by B. G. Jenkins, F.R.A.S., contains weather predictions, astronomical, sporting, legal, and domestic notes for 1909. The pamphlet is published, price 2½d., by R. Morgan, 68 Westow Street, Norwood, S.E.

"TRAVEL AND EXPLORATION."—The first number of this magazine the name of which succinctly describes its scope, contains contributions from Sir Clement R. Markham, on "A Call to Exploration," from Miss Edith Durham, on "Travel in the Balkans," and from Mr. Dudley Kidd, on "Travellers and Photography." The new periodical is most excellently illustrated, printed, and produced, though on a heavy surfaced art paper, and contains most attractive reading. It is published at 1s. by Witherby and Co., 326, High Holborn, London, W.C.

## Dew Apparatus, &c.

The Zeiss Universal Palmos Camera. Made by Carl Zeiss, Jena, and 29, Margaret Street, London, W.

A special pattern of camera, taking plates 13 x 18 c.m., or English 7 x 5 or half-plates, has been designed by the Carl Zeiss Works for use primarily on a stand, but also in the hand. The camera is of the self-contained dropping-baseboard pattern, measuring, when

closed, 9 x 9 x 3½ inches. The baseboard, on the camera being opened, is instantly latched at right angles to the ground glass, and the lens-front can then be racked out without further adjustment or separately drawn out by the spring "clips on the front of the instrument. The net result of these two movements gives a total extension of 19 inches, and the opening of the camera to this full length is a matter of only a couple of seconds. When using a wide

angle lens the baseboard is latched into a dropped position, shown in the second drawing, although the camera is racked in precisely the same way, and without any further adjustment, owing to the hinged device which attaches the front to the extension plate. The camera has rise and fall of front, both by means of the raising of the front as a whole, and also by means of a sliding lens panel. The swing front

is very conveniently adjusted by a milled screw in the centre of the baseboard, which allows the front to swing both sides of the vertical position. Built square, the camera is fitted with reversing back, which is sprung into place simply by pressure of the back against the back frame of the body, being released by pressure on two studs on the top of the camera. For use in the hand two separate focussing scales are provided, and a direct-vision finder, which is fitted with a mirror, automatically springing up into a position at an angle of 45 degrees for use when holding the instrument in a low position. The whole outfit is most substantially made in light metal, every detail being of the mechanical perfection upon which the Zeiss Works justly prides itself. The instrument is suited for all descriptions of photography for which a half-plate camera may be used, the panel of the lens front being of a size suitable for stereoscopic work. The price of the instrument complete with finder is £17 10s., dark slides of the solid pull-out pattern are supplied at 17s., a stereoscopic division for 8s., and a leather case for carrying the camera and three double slides 26s.

**The Agfa Exposure Table.** Sold by Charles Zimmermann and Co., Limited, 9 and 10, St. Mary-at-Hill, London, E.C.

A card calculator, giving exposures for the six various brands of Agfa ordinary and orthochromatic plates, is sold for the sum of one shilling. It provides for the usual variations, daily and yearly, of light, and for a wide range of subjects, and has a further novel feature in that it supplies the means of calculating the quantity of Agfa flash powder for use when using a lens of various apertures, and at various distances from the subject. Thus, for a subject at 10 yards from a lens working at  $f/6$ , the quantity of Agfa powder for a plate of 200 H. and D., such as the Agfa extra rapid, is  $2\frac{1}{2}$  gms.

**The Griffin Invisible Baby-Holder.** Sold by John J. Griffin and Sons, Ltd., Kingsway, London, W.C.

This accessory for portrait photography is a new introduction of Messrs. Griffin, and, unless we are mistaken, is identical in design with an appliance which, under a similar name, has achieved wide popularity amongst photographers in the United States. It is a species of clamp large enough to encircle or partly encircle the waist of the infant, but its form and springy material cause this embrace to be

almost humanly soft and capable of administration without the infliction of physical pain or inconvenience upon the youthful sitter. We are informed—and we cannot question the authority of Messrs. J. J. Griffin, Ltd.—that children up to six years of age may be thus invisibly held by the device. The latter can be attached to any accessory or piece of furniture, is strongly made in highly nickelled metal, and is sold at 27s. 6d., a moderate price, surely, for an appliance capable of holding a child in one place for a length of time.

**The "Trio" Aldis Lens.** Made by Aldis Bros., Sparkhill, Birmingham.

About a year ago we reviewed and described the "Duo" Aldis lens, a special front combination which when used with the back combination of an ordinary Aldis lens gives a doublet of approximately double the focal length and double the covering power. The "Trio" is a similar front combination designed to increase the focal length only one and a half times, and it is thus better suited

to cameras that will not extend sufficiently to enable the "Duo" to be used. The "Trio" submitted to us is intended for use with the well-known and popular No. 2 Aldis, Series 2, of  $5\frac{1}{4}$  in. focal length and  $f/6$  aperture. On changing the front combination for the "Trio" we have an  $8\frac{1}{4}$  in. doublet, working at a full aperture of about  $f/9$ , and, according to the makers, giving very fine definition over a 7 in. circle. As a matter of fact, however, we find it behaves very well indeed over a half-plate, and the circle is sufficiently large to enable a much larger plate to be covered with smaller stops. The corrections of this modified doublet are very good indeed, astigmatism being absent, while the field is very flat. A small point of light can be sharply focussed in any part of the 7 in. circle. As in the case of the "Duo," the spare combination is provided with a brass protecting cap, and the mounting and finish are fully up to the well-known standard set by Messrs. Aldis in their other lenses. The price of the "Trio," we are informed, will be considerably cheaper than the corresponding "Duo."

**The Penrose "Sizeometer."** Made by A. W. Penrose and Co., Ltd., 109, Farringdon Road, London, E.C.

Under this name Messrs. Penrose and Co. have introduced a useful appliance for showing at a glance the dimension length to which one dimension of an original is reduced when the other dimension is reduced to a given length. The appliance consists of a pair of graduated rules, each 17 in. in length, which open out to an exact right angle. At the hinge point a slotted rod is attached by a carrier which permits of the pair of rules being pushed backwards

and forwards when the rod is held firm. The apparatus is as simple in use as in construction. It is simply laid on the original, so that the opposite corners of the latter are seen in the slot. The angular rules are then moved up or down, as shown in the figure, until one of the arms measures the height (or width) desired. On the other arm will then be found the required measurement of the other dimension of the original. The apparatus is neatly made, and we cannot conceive of any device more handy for its particular purpose. Complete in cardboard case its price is 6s. 6d., and it may be obtained divided into either inches or centimetres.

**"WESTMINSTER" ARC LAMP—LATEST MODELS.**—We illustrate from an advance copy of the full price-list of the Westminster Engineering Co., Ltd., Victoria Road, Willesden Junction, N.W., the latest models of the firm's photographic arc lamp which we recently inspected at their works at Willesden. In addition to a number of improvements in the mechanical part of the lamps, the latter are now issued with "bottle" pattern of the glass cylinder, this form giving a better downward distribution of light than the pattern with the metal cylinder base, originally designed for cylinder printers. The "bottle" form of glass is supplied with both of the firm's standard patterns for photographic use—viz., the Nos. 111c and 114. The technical specifications of these two patterns, it may be mentioned, are as follows:—

**No. 111c Type Lamp.**—This lamp is made for burning singly on either alternating or continuous current on voltages of from 100 to 250. On continuous current, resistance must be used with each lamp.

To get the longest possible arc a regulating resistance should be used. The current is 14 to 15 amperes on 100 to 120 volts, and 10 amperes on 200 to 250 volts. On alternating current circuits a "choking coil" should be used with each lamp in preference to a resistance. With current at 3d. per unit on a 200 volt supply, the lamps taking 10 amperes, the cost of current per hour would be 6d. The lamp is suitable for portraiture, process, or printing work.

*No. 114 Type Lamp.*—This lamp is made for burning singly on either alternating or continuous current on voltages of from 100 to 500 continuous or 100 to 250 alternating. On continuous current a resistance must be used with each lamp. To get the longest possible arc a regulating resistance should be used. The current is 20 amperes on 100 to 120 volts, 15 amperes on 200 to 250 volts, and 10 amperes on 400 to 500 volts. On alternating current a choking coil should be used with each lamp in preference to a resistance. With current at

3d. per unit on a 200 volt supply, the lamps taking 15 amperes, the cost of current per hour would be 9d. This lamp is naturally more rapid and illuminates a larger space than the 111c. It is suitable for portraiture, process, or printing work.

As an example of the actinic power of the "Westminster" arc, we were interested in hearing recently of a cinematograph exposure by the Warwick Trading Company (Mr. Will. G. Barker) solely with the light of six "Westminster" arcs used for a voltage of 210 alternating current. The space illuminated was 30 ft. by 35 ft., and pictures were made at the rate of 960 exposures per minute, equal to an exposure of 1-32 of a second for each photograph, as there is a half period of darkness to be allowed for the movement of the film in the camera. The lens was working at  $f/4.5$ , and the speed of the emulsion was about 195 H. and D.

**CHRISTMAS HOLIDAYS.**—Messrs. J. H. Dallmeyer, Ltd., inform us that their factory at Neasden will be closed from Thursday, December 24, to Monday, January 4, to allow of the usual overhauling and cleaning of the factory and machinery. Their showrooms at 25, Newman Street, W., and offices at Denzil Road, Neasden, N.W., will however, re-open as usual on Monday, December 28, and Tuesday 29 respectively.

## New Materials, &c.

"CARBONA" CLEANSER FOR OIL-PIGMENT BRUSHES.—Messrs. John Morgan, Richards, and Sons, Ltd., 46, Holborn Viaduct, E.C., send us a sample of a liquid supplied by them as a substitute for benzole and light petrol, over which products it possesses the advantage of non-flammability whilst still exerting a powerful solvent action on greasy or fatty bodies. We have found it to act as a most effective cleanser of the brushes used in the "oil" and "bromoil" processes, and we have likewise failed to cause ignition of the liquid or of its vapour under such conditions as could prevail in ordinary circumstances. For many other cleansing purposes "Carbona" should be found useful in the professional photographer's studio; since it removes grease from fabrics, etc. It is obtainable in bottles, from 7½d.

### CATALOGUES AND TRADE NOTICES.

**DIFFRACTION GRATINGS AND SPECTROSCOPES.**—Messrs. R. and J. Beck, 68, Cornhill, E.C., have issued a catalogue of Thorp diffraction gratings and other spectroscopy accessories, which they can supply mounted specially for photographic purposes. The list includes pocket and table Beck-Thorp spectroscopes, and is sent free on application.

**"THE PRISM"** (A. E. Staley and Co., 19, Thavies Inn, E.C., for one penny stamp), in its current issue, describes the many branches of work in which an anastigmat lens of large aperture, such as the "Tessar," is almost a necessity.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

#### MONDAY, DECEMBER 28.

South London Photographic Society. "Home-made Apparatus." Members.

#### TUESDAY, DECEMBER 29.

G.W.R. Literary Society (Photographic Section). "On the Printing, Developing, and Toning of Velox Papers." W. F. Slater.  
Blackburn and District Camera Club. Members' Enlarging Night.  
Hackney Photographic Society. "Colour Projection." S. W. Morrison.

#### WEDNESDAY, DECEMBER 30.

North Middlesex Photographic Society. Technical Meeting. Nomination of Officers and Council for 1909.  
Croydon Camera Club. Conversational Evening.  
Croydon Gas Camera Club. "On the Printing, Developing, and Toning of Velox Papers." W. F. Slater.  
Leeds Camera Club. "Development of the Negative." F. Rust.

#### THURSDAY, DECEMBER 31.

Melbourne (Dulwich) Camera Club. "Copying by Artificial Light." P. Fredk. Visick.  
Richmond Camera Club. Lecture by Major Latham.  
North-West London Photographic Society. 1908 Collection Affiliation Slides.  
Watford Camera Club. "On the Printing, Developing, and Toning of Velox Papers." W. F. Slater.

**CROYDON CAMERA CLUB.**—At the invitation of the club nearly twenty members of the medical profession practising in Croydon and neighbourhood assembled last week to hear a joint lecture by Dr. C. E. K. Mees and Mr. W. H. Smith, on X-rays, their various applications, and the necessary apparatus for their production, an abstract of which we hope to publish at a later date. It will be sufficient to say here that a solid two hours of compressed matter was listened to with the greatest attention and interest, the only one present whose appreciation was of a modified nature being the honorary reporter, who, ignorant of shorthand, inwardly prayed at intervals for the intervention of blackboard diagrams, to enable him to "catch up."

The appearance of Dr. Mees and Mr. Smith, accompanied by a small cartload of apparatus, was due to the ingenuity of the club's

honorary secretary, Mr. H. M. Bennett, who had successfully tackled and solved a problem which must present itself frequently to secretaries in general. To illustrate this problem and its solution an impersonal case may be assumed. Let A B and C D be members of a society who have a knowledge of any given subject. Both are independently asked to lecture on that subject, and respectively decline, for reasons satisfactory to themselves and no one else. An interval is allowed to elapse. A B is then approached by the hon. sec., who, comforted by the doctrine of the "means justifying the end," states that C D is willing to give a lecture if A B will afford a helping hand. It would be ungracious to refuse, and this is agreed upon. C D is then interviewed and told that A B has kindly consented to lecture if he (C D) will render a little assistance, which in turn is cheerfully promised. Time goes on, and, prior to the date fixed, A B and C D meet to arrange details. "In what way can I help you?" says A B, politely, to C D. "Pardon me," replies C D, "it is I who propose helping you." The question being further discussed between the two, a distinct danger at this point arises, that both may come to the conclusion that they have been very badly "had"; but "extreme regrets" on the part of the responsible official, "that any unfortunate misunderstanding should have arisen," will probably smooth matters over, and result in a joint lecture being given, to the satisfaction and gratification of all. *Verb. sap.*

## Commercial & Legal Intelligence.

**ST. BLAZEY PHOTOGRAPHER'S DEBTS.**—W. J. Osborne, photographer, St. Blaze, applied, at the St. Austell County Court, for an administration order to enable him to pay his debts, amounting to £25, at the rate of 15s. in the £ by instalments of 6s. per month. Debtor ascribed his position to lack of capital, pressure of creditors, business depression, and some person or persons exposing him to the public at large, through which his business had practically come to a standstill.

Captain W. Williams, mine manager and furniture dealer, of Station Road, St. Blaze, appeared as a creditor to object to the order being granted. He said defendant had employed a man during the past summer on a basis of 20 per cent. commission on sales, and that person he could prove had been receiving 15s. per week from applicant, thus leaving Osborne an income of £3 per week to enable him to pay 15s. in the £. That man had now left applicant, but he still had another man to assist him. Osborne did good business in the neighbourhood. Applicant denied that he employed a man at 20 per cent. He only employed him between times, and was paid by a mutual arrangement. It was merely a friendly action.—His Honour: A good friend that. What did you pay him, putting aside friendship?—Osborne: I might have paid him 4s. to 5s. per week, perhaps 6s. or 7s. sometimes. He agreed with his Honour that summer was the best time for his business.

Captain Williams complained that applicant had not included all his debts, pointing out that he owed a debtor called Courtney an amount of 16s. 6d., besides other people, whom he agreed to pay in full.—Osborne said he was not aware he owed Courtney anything. The debt referred to, for picture framing, Osborne said he had settled by giving the man a picture framer's vice.—Captain Williams also pointed out that the Official Receiver was applying for the payment of £2 from Osborne owing to Mr. Eplett, of St. Blaze, whose affairs are in bankruptcy.—Osborne said that was nothing to do with commission payable to Eplett; it was money lent him at the time.—Captain Williams again stated that he could prove there were some accounts Osborne had not turned in at all, and which Osborne proposed to pay in full.—His Honour said if that could be found out that was another question.—Osborne protested that Captain Williams knew more about his business than he did himself, whereupon Captain Williams retorted that he only went by facts.—His Honour pointed out that debtor only owed £25, and that there was plenty of margin for people who had any more accounts against him.—His Honour decided to make the order.

**LEGAL NOTICES.**—An adjudication order has been made against Alfred Fletcher, photographer and picture framer, of The Studio,

Town End, Chapel-on-le-Frith, Derbyshire. The receiving order was made on December 10.

A receiving order has been made against John Walter, proprietor of a photographic art gallery, 49, Southampton Row, W.C., and lately carrying on business as a partner in the firm of Burnbaum, Walter and Co., egg importers, of 42, The Exchange, Southwark Street, S.E. The petition was filed by a creditor on November 13, and the receiving order was made on December 14.

## News and Notes.

**THE HOUGHTON SMOKER.**—On Friday evening, December 18, at the Holborn Restaurant, the third of the series of smoking concerts organised by the London staff of Messrs. Houghtons Ltd. was held, Mr. Edgar W. Houghton presiding over a crowded attendance. Arranged primarily by the staffs of the Houghton establishments, and enthusiastically organised and supported by them, the function has, however, acquired also the character of an annual Christmas re-union of many associated with the photographic trade. Among those who last Friday were numbered among Messrs. Houghtons' guests were Messrs. Hubert Elliott and F. E. Greenwood, H. W. Hall and J. B. B. Wellington, Thomas Illingworth, A. E. Staley, Chas. Zimmermann, R. J. Kindon, W. Thomas, W. T. F. Wastell, J. McIntosh, B. Foulkes-Winckes, C. Winter, C. F. Lan-Davis, J. E. Hodd, A. W. Brooks, H. C. Pharaoh, L. J. Bolton, Percy Barringer, and George E. Brown. Mr. Edgar Houghton, who was supported by Messrs. Charles Houghton, F. C. Smith, Percy G. R. Wright, and other officers of the firm, introduced to the audience a company of vocal and instrumental entertainers, on the selection and direction of whom every congratulation may be offered to Mr. Paul Payne, who, as in previous years, was responsible for the programme, and the hour was not far short of midnight when a most enjoyable evening was brought to close by spontaneous cheers for the chairman and calls for a speech. Mr. Edgar Houghton, in briefly responding, expressed his thanks for the marks of cordiality on the part of those present, and with this evidence of the excellent relations between all those engaged in the Houghton business, the evening was brought to an end by a vote of thanks to Mr. Payne and the performers. During an interval a collection of £8 12s. 6d. was taken for the "Referee" Children's Christmas Dinner Fund.

**MR. J. ARNALL**, of 9, Boulevard Bonne Nouvelle, Paris, has been awarded a gold medal at the Salon Mobilier et Arts Decorative.

**THE WANDSWORTH BOROUGH COUNCIL** passed plans on December 16 for the erection of a photographic studio at 298, Streatham High Road.

**PROFESSOR LIPPMANN** has been honoured by the award of one of the Nobel prizes. The distinction is granted for his researches in colour photography.

**THE BLACKPOOL TOWN COUNCIL** are endeavouring to obtain further power to deal with the large number of street hawkers, itinerant photographers, and others, who swarm into Blackpool during the visiting season.

**JAPANESE DECORATIVE ART.**—Those interested in the art handicrafts of Japan and in the mythology of that country which is invariably associated with them, may be glad to be referred to two articles by Mr. H. G. Ponting on "The Adornment of the Sword," which appeared in recent issues (November 14 and December 12) of "Country Life."

**SHEFFIELD PHOTOGRAPHIC SOCIETY.**—The sixth annual exhibition will be held in the Montgomery Hall, Sheffield, from March 30 to April 3, 1909. There will be six open classes (including one for colour photography), all of which are open to both amateurs and professionals, and the judging will be done by Mr. C. F. Inston, F.R.P.S. Exhibitors at the Nottingham Camera Club's exhibition, can have their pictures forwarded to Sheffield free of charge if

desired. Entries close March 13, 1909, and we believe entry forms will be ready shortly, but in the meantime full particulars may be obtained from the hon. sec., Mr. H. Merrill, 22, Harboard Road, Woodseats, Sheffield.

**COLOURING ELECTRIC LAMPS.**—C. Kemsey-Bourne writes to the "Pharmaceutical Journal": "After considerable experiment, I decided to use the following, which so far has proved satisfactory. The solution dries very quickly, gives a clear sparkling colour, and takes practically no time to make or to use. Mawson's enamel collo-dion is thinned with methylated ether and coloured with aniline dyes. To use, hold the lamp over a suitable vessel and simply pour the solution on. The shape of lamp lends itself to this method.

**THE TROUBLES OF AN EDITOR,** as enumerated by the "American Druggist," are quoted here for the benefit of various readers:—"Editing a newspaper is a nice thing. If we publish jokes people say we are rattlebrained. If we don't we are fossils. If we publish original matter they say we don't give them enough selections. If we give them selections they say we are too lazy to write. If we don't go to church we are heathens. If we do go we are hypocrites. If we remain at the office we ought to be looking out for news items. If we go out we are not attending to business. If we wear old clothes they laugh at us. If we wear good clothes they say we have a pull. Now, what are we to do? Just as likely as not someone will say that we stole this from an exchange. So we did. So did he."

**THE SERVICE COMPANY, LTD.**—The report of the Service Company, Ltd., for the year ending September, 1908, shows that the gross profit, which amounts to £5,342 12s. 1d., is the largest ever made by that company. After paying the dividend on the 6 per cent. preference shares £409 has been carried to reserve, and £177 to next year's accounts.

In order to meet the requirements of their increasing business the service company have had an additional exchange line, and their telephone numbers will in future be 260 Central and 2,071 City. It is hoped that this, combined with the fact that a number of internal extension telephones have been fitted up to the different departments, will enable their customers to transact their business "over the 'phone" more expeditiously than they have been able to do in the past.

**MR. THOMAS BEDDING.**—We learn from the current issue of "The Photo Miniature" that Mr. Thomas Bedding, who had been associated for the past few months with Mr. John A. Tennant in the editing of our contemporary, has taken charge of the experimental research department of the Cameraphone Company, of New York, one of the largest and most progressive houses in the moving picture world.

**THE INEBRIETY OF ART.**—A simple rustic (relates the "Windsor Magazine") coming across an enthusiastic lady artist sketching a small landscape with a large sky, took a respectful interest in the picture.

"Ah," said the lady, "perhaps to you, too, Nature opens her sky-pictures, page by page. Have you seen the lambent flame of the dawn leaping across the livid east—the red-stained, sulphurous islets floating in lakes of fire in the west—the ragged cloud at midnight, black as a raven's wing, blotting out the shuddering moon?"

"No miss," replied the man, "not since I quit drinking."

**AN "AUTOTYPE" CALENDAR.**—One of the most useful pieces of trade literature we have seen for a long time is the calendar just issued by the Autotype Company, and presumably obtainable by sending one penny stamp to 74, New Oxford Street, London, W.C. The calendar bears a pair of Autotype carbon prints of children's portraits, a calendar with monthly tear-off, and a useful "at-a-glance" indicator, a tiny frame, which travels in both directions over the calendar, and can thus be adjusted each day to point out the date.

**ST. HELENS CAMERA CLUB.**—The eighth annual exhibition will be held in the Windle Pilkington Hall, St. Helens, from February 8 to 13, 1909, when the judging will be in the hands of the Rev. H. W. Dick and Mr. C. F. Inston, F.R.P.S. There will be four open classes, three of which will doubtless attract special attention—namely, the championship class for pictures that have taken awards in open

exhibitions during the last three years; a class for pictorial photographs which have never previously won a prize; and the class for colour photography. In each of the first two awards to the value of one guinea and a half a guinea will be placed at the disposal of the judges; in the third one prize, value 10s. 6d., is offered. Entries close January 27, on or before which date entry forms, together with entrance fees must reach the hon. sec., Mr. A. G. Else, Duke Street, St. Helens, from whom entry forms and full particulars may also be obtained. Intending exhibitors at the northern exhibition should note that their pictures can be conveyed from Manchester to St. Helens free of charge.

**THE "CHEMIKER ZEITUNG."**—We are informed by a circular that the "Chemiker Zeitung," the organ for over thirty years past of the German chemical industry, will, from January 1 next, appear three times, instead of twice, a week. The "Chemiker Zeitung" must thereby make a record in technical journals, and the value of its pages to technical and scientific chemists thus receives a further proof. It may be added that photo-chemistry and photographic chemistry figure in its "Repertorium," or abstracts of current progress.

**CHALLENGE COMPETITION.**—The awards made by Messrs. Backhouse and Coppock, Ltd., in the competition recently organised by them for users of the "Challenge" printing papers are as follows:—First prize, gent.'s Rudge-Whitworth cycle, awarded to Mr. W. Cheetham, 10, Malpas Street, Oldham; second prize, high grade English camera, plate, by Thornton-Pickard Company, Mr. H. J. Blane, 67, Minard Road, Catford, London, S.E.; third prize, £1, Mr. Charles J. Hankinson, Birken, Bournemouth, W.; fourth prize, 10s., Rev. E. Travers Clark, Tiverton, Devon. The high standard of the results made it no easy task to award the prizes.

## Correspondence.

- \**Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*
- \**We do not undertake responsibility for the opinions expressed by our correspondents.*

In consequence of pressure upon our space and the earlier closing of the pages owing to the holidays, several letters are held over.

### A WARNING.

To the Editors.

Gentlemen,—As a warning to readers, it may serve a purpose if the trick adopted in stealing a quarter-plate Newman and Guardia high-speed universal camera (No. 1,237) and Zeiss planar lens (No. 38,011), which had been advertised, be published.

The thief called, saw the camera, and obtained visiting card of owner, promising to call again. This he did when he knew the owner to be absent.

Showing the card as evidence of a message (sic), he presented a dummy parcel, and was allowed to take the camera in exchange.

It seems absurd to have to point out that a visiting card, supported by however plausible a story, is no evidence of an authentic message.

Thanking you in anticipation for the publication, I am, yours truly,

T. F. CONNOLLY.

53, Bradbourne Street, Parson's Green, W.

### BROMOIL DEMONSTRATIONS.

To the Editors.

Gentlemen,—May I explain that the error which you pointed out on p. 958 of your journal is purely a verbal one, due to a mistake on the part of my secretary in typing my manuscript, which resulted in the word "when," instead of "by," being inserted immediately preceding "Mr. F. J. Mortimer," and in the substitution (three

lines below) of "favoured" for "favouring"? I have, of course, not forgotten Mr. Welborne Fifer's memorable demonstration at the R.P.S. in January, 1908.—Faithfully yours,  
Cheam Road, Sutton.

HECTOR MACLEAN.

December 19, 1908.

### STEREOSCOPIC PROJECTION.

To the Editors.

Gentlemen,—In response to your invitation to supplement my previous letter I might state that I made up no particular strength of iodine solution. It was, however, made up in accordance with the method you mention, except that I added a few ccs. of alcohol before adding the water. To remove the free iodine and to clear the high-lights after staining, I used a 10 per cent. solution of sodium sulphite. This solution is also useful for removing the red and green dye from fingers and nails should they become stained. The dye solutions were made by dissolving half a grain of either dye in eight ounces of water. The strength of these solutions is really immaterial, as the same result appears to be obtained by a long immersion in a weak solution or a short immersion in a strong solution. I prefer, however, a weak solution, as the high-lights are more easily cleared.

In making up the aniline green solution I found it advisable to dissolve the dye in a small quantity of water with constant stirring, then allowing to stand for ten minutes or so, and finally pouring off to about half an inch of the bottom. If this is not done minute particles appear to remain in suspension, and gradually settle on the film, causing dark green spots, which are very difficult to remove. For fixing, I used a 10 per cent. solution of hypo. Fixation is very quick, apparently one or two minutes being sufficient. It is necessary to dissolve out the silver iodide image, as it is more or less opaque, and can thus be seen by both eyes, regardless of the coloured spectacles, when the picture is projected. After fixing the slides were washed in several changes of water. It is better not to employ running water, but to let them soak at the bottom of a dish, as the image is thus less likely to be washed out.—Yours faithfully,

33, London Road, Ipswich.

HARRY DE BEER.

December 21, 1908.

## Answers to Correspondents.

- \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.
- \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- \* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.
- \* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

### DRAWINGS REGISTERED:—

- J. ANDER, 3, Benwell Grove, Newcastle-on-Tyne. Drawing (Combination) containing Three Black and White Sketches of H.M.S. "Calhops," with a Scroll giving an Account of the Vessel.

**POSITIVE TRANSPARENCIES.**—I should be glad if you would kindly let me know what developer for plates you would recommend to produce the best quality positives from, as I want to send some negatives to a firm to have a lot of copy negatives made from them, and should like the best results possible. Should the negatives be thin, with plenty of detail?—J. T.

We would tell you that the best results are obtained from positive carbon transparencies. Using dry plates, there is no appreciable difference between the different developers. We should use one such as Rodinal, with which it is easy to get a soft

positive, as it is this quality of transparency which is necessary. There should be no absolutely clear glass, detail everywhere, but no excessive density in the shadows—in short, a flat-looking transparency compared with a good lantern-slide.

**COLONIAL PHOTOGRAPHS.**—Could you please tell me in your "Correspondence" column if I could get photographs of the colonies (Canada, Australia, South Africa, etc.) from any publishing house in London? If not, how could I obtain them?—GEO. RIDDICK.

Apply to a large firm of photographic view publishers, such as Valentine, 154, Perth Road, Dundee; Photochrom, Ltd., 35-36, Hosier Lane, Snow Hill, E.C.; or you could no doubt obtain stereoscopic photographs from Underwood and Underwood, 3, Heddon Street, Regent Street, W.

**INQUISITIVE.**—We advise you to get the two books on the subject by Whiting (Dawbarn and Ward, 1s.) and Drinkwater Butt (Hiffe, 1s.). You would also greatly benefit by taking practical lessons, either personal or through the post, as offered by Mr. T. S. Bruce, 4, Villas-on-Heath, Vale, Hampstead, N.W.

**RETOUCHING MEDIUM.**—Will you kindly tell me what properties or effect the asphaltum has in retouching medium? Has it a hardening, or simply to colour (p. 790, "B.J. Almanac")? I have also had the other medium made up at a local chemist (p. 588, "Almanac," 1909); when applied appears hard and smooth surface, but when the finger is run across it leaves a mark as though there was too much oil, dulled, but not noticed on looking through if it dried quickly, as stated, it would not mark whichever way you rub your finger across after it has had time to dry. I usually rub it over with a silk cloth to remove the excess and give it a tooth, but you still see the faint marks where the finger is run over, do you think there has been too much oil added, or is that the nature of this particular formula?—MEDIUM.

Asphaltum is added to retouching medium to give it "tooth"—i.e., the property of taking heavy work without picking up. The soft asphaltum used in making black japan, and not rock asphaltum, is to be preferred. We have examined the sample of medium sent, and compared it with that recommended on p. 790 of the "Almanac." It does not take so much work as the latter, and also "picks up" under heavy work. Castor oil, oil of lavender, spike (i.e., oil of lavender and turpentine mixed), linseed oil, etc., have this unfortunate property. The marking referred to we do not notice, and must assume your method of application is incorrect. In his book on retouching, Mr. Arthur Whiting says: "See that it (the negative) is thoroughly dry and quite free from dust, then apply the retouching medium with a piece of silk or cambric, thinly all over the film. Let the cambric be drawn over the finger-tip without creases, and just touched against the cork of the medium bottle (after the bottle has been shaken once). Then with a gentle circular motion apply as above. Do not rub; do not put the medium on thickly or so that it leaves lines, streaks, or marks." In conclusion, we may mention that with a good medium, correctly applied, the retouching pencil will "sing" at work, especially if being used at considerable speed.

**SPIRIT LANTERN-SLIDES.**—I shall be glad if you will let me know if lantern-slides of any of Archdeacon Colley's spirit photographs are on sale, and, if so, where they can be obtained; if not, can you give me his address?—A. E. A.

So far as we know, they are not published. If they are, you could get them through Newton and Co., 1, Fleet Street, E.C. We do not know the address of Archdeacon Colley.

**GASLIGHT PAPER DEVELOPERS.**—Re above, in December 11, I note you state that there is a well-known amidol formula which is practically successful with all gaslight papers. If you will kindly give me the formula you refer to you will do an old reader a favour.—PUBLICO.

You have not read our note quite correctly. We do not refer to any particular formula, only to the well-known fact that one good formula will work well with practically all the gaslight papers. Each worker usually has what he considers to be a good formula, and he very seldom changes it, in spite of all the recommendations of the paper-makers. We have used many different formulae, some made up to our own ideas, and some bought ready-made, and our experience is that the final result is much the

same, whatever the brand of paper may be. The main difference is in time of action. The amidol developer that we favour most is not, strictly speaking, amidol at all, but diamidophenol, which is now much used in place of amidol. The formula is as follows:

Soda sulphite .....	1 ounce.
Potass metabisulphite .....	1 drachm.
Diamidophenol .....	40 grains.
Potass bromide .....	5 grains.
Water to .....	20 ounces.

With papers that develop very rapidly we sometimes dilute this to half-strength, but as a rule we find it works well with all papers.

**SECOND LENS.**—To-day I managed to pick up a lens bearing the following inscription, and I should be glad if you would let me know if it is of any value, and for what camera it could be used? It appears to be of about 6in. focus: "Doppel anastigmat, D.R.P., Serie III./0, F120m/m, No. 35,277. C. P. Goerz, Berlin." If it has any value, what is the best means of getting it sold, as I have no use for it?—HIGHLAND.

The lens is marked as a Goerz anastigmat, and if it is a genuine example of the firm's manufacture it is certain to be a very fine lens of aperture  $f/6.8$ . But we would caution you as to spurious Goerz lenses, which have been offered second-hand, particularly in Glasgow. Your best course is to address the C.P. Goerz Optical Works, Ltd., 4 and 5, Holborn Circus, E.C., asking them to confirm the particulars you give.

**S. E.**—If you state your wants to Messrs. Penrose and Co., 109, Farringdon Road, we think they could supply you.

**F. C. B.**—We have never made comparative tests, but we should put it at slower than 1-20 or 1-30, more like 1-100. Except with a thin negative, high-power light, and a lens of large aperture, enlarging on gaslight paper becomes tedious. Why not use bromide paper.

**H. E. W. V.**—The fact mentioned to you is one which is a very frequent cause of stains, and such effects are produced in a most erratic manner. The prints should certainly not show discolouration on the backs before toning.

**MILTON.**—If you apply to the Comptroller, Patent and Trade Marks Office, Southampton Buildings, you will obtain the necessary forms. The cost of registration is £1.

**BERNARD JONES.**—So far as we know, no draft has yet been published. We have obtained our information from Berlin.

**VARNISH.**—In making varnish, according to two of the formulæ given in the "Almanac," I find a difficulty in getting the white lac to dissolve freely, and when it does dissolve it leaves a sediment behind and the solution remains turbid. It also takes a long time to filter. I shall feel obliged if you can tell me the reason of this.—H. C. JONES.

There may be more than one cause for the difficulty. One may be that the lac has become more or less insoluble by keeping. White lac should be used freshly bleached, as it has a tendency to become insoluble by keeping, particularly if it is not kept in a somewhat moist condition. Another may be that the spirit employed was too weak for the purpose. For the solution of shellac, sandarac, and other resins the strongest spirit obtainable is best. Bleached lac usually contains a certain amount of water left in the bleaching operation, and that tends to weaken the spirit. Before dissolving white lac it is a good plan to break it up and dry it before putting it in the spirit. If the varnish remains turbid long after the resins are dissolved it may often be cleared by putting the bottle containing it in a vessel of warm water for a time.

**STEREOSCOPIC PHOTOGRAPHY.**—I have recently taken some fairly good stereoscopic pictures with my quarter-plate camera. I have a board with parallel fillets of wood on it, between which I can slide the camera up to three inches, and it answers all right. What I wish to ask you is, will this arrangement do as well for interiors as a camera with two lenses, as I wish to take some stereoscopic pictures of two or three darkly lighted interiors of churches close by here, or is a bi-lens camera absolutely necessary for this kind of work?—A. BOSE.

The arrangement you have been using will do quite well for interiors, so far as the stereoscopic effect is concerned. The diffi-

culty you will have to contend with is that of getting the two negatives, with a long exposure and possibly varying light, equally timed. It is here that the bi-lens camera is at a great advantage over the single lens one. However, a slight discrepancy in the depth of the two halves of a stereoscopic transparency is not of any very great moment, as in the stereoscope this will not be noticeable.

**A. B.**—If the man to whom you gave the order is the accredited agent of the firm the latter is bound by any agreement he may have made with you, and it is he you must proceed against. We know nothing whatever of the firm, nor had we heard of it before. It may be possible that the Professional Photographers' Association knows something about it, and if you are a member we should advise you to communicate with the hon. secretary, at 89, Albany Street, N.W.

**T. BOWEN.**—The spots are clearly due to particles of iron coming in contact with the prints while they have free silver in them, as when they are being washed before they are toned. The only way of avoiding them is to filter the water before use. This is easily done by tying a couple of thicknesses of fine flannel loosely as a bag over the tap. This will, of course, require changing occasionally, as it gets charged with iron rust from the pipes. When water passes through old iron pipes it is very prone to be charged with small particles of iron rust.

**LONDON COUNTY COUNCIL SCHOOL OF PHOTO-ENGRAVING AND LITHOGRAPHY.**—The annual supper of this flourishing school took place last Saturday night in their own "art room," which was crowded with men and youths, past and present students, and many distinguished guests. In a thoroughly Bohemian way the company regaled themselves upon mutton and beef, whilst ale was served from large spouted cans. Heartiness was the order of the evening, as it always is at these functions, and the unceremonious manners of the students seemed to increase the enjoyment of the big guns at the cross table. Youth is youth and students are students all the world over, and it scarcely came as a surprise when one of the speakers was interrupted by a suffragette holding aloft a banner, inscribed "Votes for Women." The speaker and the chairman, Sir George Frampton, both entered into the spirit of the joke, advising care in the removal of the obstructionist. The distinguished visitors indulged in much complimentary toasting of each other, and everybody seemed to receive musical honours. The speakers were Sir George Frampton, R.A.; Messrs. A. J. Newton and Cecil Rea, vice-chairmen; Dr. Wm. Garnett, secretary of the Education Committee, who gave a most succinct account of the development of art teaching; Dr. C. W. Kimmins; M. Nelson Dawson; Frank Colebrook; and A. B. Sullivan. The unconscious humour of the last was a great delight to the audience. A varied entertainment followed the distribution of prizes, the chief recipient of which was a talented student, Peter by name. A badge of silver, presented by the chairman, was won by Mr. Barber for the best work of the year. Drawings and sketches of a very high order of merit lined the walls, and evinced, not only technical and academic skill, but fine imaginative and romantic feeling, remarkable as coming from London boys trained in a little court off Fleet Street.

\* \* NOTICE TO ADVERTISERS.—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears on the last portion of the paper.

### Situations Wanted.

**ADVERTISER**, well-known portrait medallist, and one who has had a large clientele among the nobility, wishes to hear of either a Partnership as active Managing Operator or as Manager Operator in good house. Total abstainer. Only first class applications considered.—J. 6, 24, Wellington Street, Strand, London.

**AS** Operator-Retoucher or Branch Manager; good class quick trade; first-class exp. with dark-room, Bromide, and outdoor work; competent and energetic; disengaged.—"B," 17, Manbey Grove, Stratford, E.

**A** FIRST-CLASS Retoucher requires Engagement, London or suburbs; willing and obliging.—D. Gassman, 18, Tenter Buildings, St. Mark's Street, Aldgate, E.

**AS** Improver.—Youth (16) requires Situation, architectural; 9 months' exp.; can operate and develop; Bromide; attending Polytechnic; small salary.—"D. O.," 233, Essex Road, Canonbury, N.

**A** GENTLEMAN of sound practical business ability disengaged; managing operator; high-class work only; many years' West-End experience; exceptional refs.—J. 9, 24, Wellington Street, Strand.

**AS** Operator-Retoucher.—Young Gentleman, with 12 years' all-round experience, desires Engagement with good-class firm. Refs., spec., etc., from "C. G. H.," 57, Walpole Rd., Boscobel, Bournemouth.

**A** N experienced Lady Retoucher, good and quick worker, desires Engagement; would assist generally if required. Spec. and ref.—"Pencil," 98, Woodland Street, Dalston, London, N.E.

**A** THOROUGHLY experienced Technical and Commercial Photographer, with practical knowledge of process work and block-making, wants Situation; low salary.—J. 13, 24, Wellington Street, Strand.

**AS** ASSISTANT Operator and Developer seeks Berth; accustomed to Bromide and gaslight printing; 6 years' experience; good refs.; age 21; no Sunday duties; perm.—"A. M.," 28, Hemstead Road, West Hampstead, N.W.

**AS** ASSISTANT Operator-Retoucher desires Re-engagement; 10 years' experience in first-class firms; Liverpool or Leeds preferred.—J. 16, 24, Wellington Street, Strand.

**AS** ASSISTANT (age 21) requires Situation in first-class house, where he can learn operating; first-class retoucher; also developing and copying.—Leslie Hart, Morfa Nevin, N. Wales.

**AS** ASSISTANT Operator and Retoucher; 7 years' experience; good references; London preferred.—Address "C. S. H.," 3, Garfield Terrace, Paignton, Devon.

**AS** ASSISTANT Operator-Retoucher desires permanent Berth in good house; willing to assist all round; good refs.—A. Prescott, 7, Walton Crescent, Oxford.

**A** THOROUGHLY practical Operator-Retoucher and Finisher in B. and W. seeks Berth; used to electric light, etc.—Address "M.," Carlton Studio, 34, New Cross Road, S.E.

**A** LADY desires Berth as Retoucher and Finisher, thoroughly experienced, and could assist other branches; good refs.—"W.," care of Mrs. Lewry, 98, Kensington High Street, W.

**B** ROMIDE Printer and Enlarger wants Berth, London or suburbs; experience with best firms; specimens and references; 35s.—J. 26, 24, Wellington Street, Strand.

**B** ROMIDE Enlarger, Printer (all processes), Operator, and General Assistant requires Berth; artistic posing and lighting; moderate salary; good references, etc.; London or suburbs.—Barlowe, 63, Buckingham Road, Willesden Junction, N.W.

**B** RANCH Manager, Operator and Retoucher, desires Situation; capable, steady, and industrious; 5 years in this situation.—Robinson, 68, Bloomfield Road, Plumstead, S.E.

**D** ARK-ROOM Assistant, thoroughly competent, desires Berth with good London firm, or would assist generally; well experienced in commercial work; mod. salary for perm.—"D.," 2, Camble Road, Tooting.

**D** ARK-ROOM and Studio Assistant desires Berth with first-class firm; thorough West-End experience as developer and printer; London preferred; salary, 25s.—"E.," 46, Greyfriars Rd., Reading, Berks.

**D** ISENGAGED, all-round hand (22), for high-class work; knowledge of retouching; 7 years' experience.—For particulars and references apply "N.," Garfield Studio, Paignton, S. Devon.

**F** IRST-CLASS Assistant Operator-Retoucher; good modeller, knife; expert developer.—"F. S.," 83, Fore Street, Ipswich.

**G** ENERAL Assistant (21) requires Situation in first-class house; thoroughly exp. in Carbon, Plat., C.C. etc., and retouching; ex. refs.—"C. K.," Wensley House, South Road, West Hartlepool, Durham.

**G** ENERAL Assistant seeks Re-engagement, or temporary employment; 20 years' experience in all branches (including Autochrome).—Address "Photo.," 94, Stephendale Road, Fulham, S.W.

**G** ENERAL Assistant requires Post; exp. Printer, Aristo, P.O.P. and Bromide; operate, develop, enlarge; also tinting; knowledge of Carbon and Plat.; ex. refs.; Wales preferred.—Phelps, Johnstown, Carmarthen.

**G** OOD Bromide Printer seeks Situation; used to all classes of work; developing, operating, etc.—Address Peters, 6c, Della Street, Wandsworth, London, S.W.

**G** OOD Finisher desires Re-engagement; good worker in small Plats., Carbons, and copies; knowledge of Aërograph; good references.—J. 46, 24, Wellington Street, Strand.

**I** MPROVER.—Young Lady, with good knowledge of high-class photography, requires Berth where opportunity would be given to learn retouching; efficient at mounting, spotting, printing, etc.—Address J. 31, 24, Wellington Street, Strand.

**L** ADY as Receptionist, Book-keeper, Correspondent and Finisher, disengaged January 15; excellent references; permanency only; London or suburbs preferred.—J. 37, 24, Wellington Street, Strand.

**L** ADY requires Position as Receptionist; permanent; Liverpool or Manchester preferred; accustomed to high-class work; in present sit. 3 years; good colourist.—J. 3, 24, Wellington Street, Strand.

**L** ADY desires Re-engagement as Retoucher; 5 years' experience in business.—A. Marriott, 19, Woburn Place, Russell Square, London, W.C.

**M** ANAGING Operator desires Engagement in high-class studio; or would purchase good studio on terms.—J. 17, 24, Wellington Street, Strand.

**M** ANAGEMENT.—Operator and wife require appointment to manage Branch, or otherwise; thoroughly practical throughout; disengaged.—T. Lyons, care of Post-Office, Haidleigh, Essex.

**N** ORWEGIAN Lady, long experience in retouching, wants employment in first-class studio; small salary required.—"W.," Brunswick House, Clifton Gardens, Maida Vale, W.

**O** PERATOR (28), married, wants Re-engagement, or permanent; usual salary and commission; average 22; day-electric; coupons; reliable.—Write "Photographer," c/o 41, St. John St., Longsight, Manchester.

**O** PERATOR, age 30, day, electric light, and at-home portraiture; good retoucher; experience gained in leading studios.—"Photographer," 21, Churchill Road, London, N.W.

**O** PERATOR-RETOUCHER desires Berth with first-class firm; disengaged; could manage.—Address 78, Chesherton Road, North Kensington, W.

**O** PERATOR and Retoucher, used to management; printing in all processes; West-End experience; outdoor and interior work.—"Manager," 1, Macroon Road, St. Peter's Park, W.

**O** PERATOR and Assistant Retoucher desires Berth in good house; printing in all styles; could manage branch.—"Operator," 230, Mitcham Road, Tooting, S.W.

**O** PERATOR of ability, studio or out, open to engagement; well up in all processes; Carbon, etc.; and successful with children; retouch if required.—Brooke, The Nest, S. Benfleet, Essex.

**O** PERATOR-RETOUCHER, used to management; West-End experience; long references; good outdoor and Bromide hand; London preferred.—"F. P.," 91, Davenport Road, Catford.

**O** PERATOR-RETOUCHER-MANAGER, thoroughly experienced, has successfully managed branch for 7 years; first-class references.—"C.," 22, Rosebery Avenue, West Bridgford, Nottingham.

**O** PERATOR-RETOUCHER; has had management, long experience in good-class quick trade; day and electric; good references.—"R.," 28, Almeida Street, Upper Street, N.

**O** PERATOR or Assistant Operator in first-class studio, with chances of improving retouching; of gentlemanly address; speaks both French and English.—J. 39, 24, Wellington Street, Strand.

**O** PERATOR-RETOUCHER desires permanency as Manager of Branch; over 7 years thorough all-round exp.; age 24; abstainer; thoroughly competent and reliable man; refs.—"Manager," 23, Elworth Street, Sandbach, Cheshire.

**O** PERATOR, thoroughly experienced in commercial work, catalogue illustration, etc.; knowledge of enlarging and retouching; can finish own work.—"B. S.," 8, Montpelier Road, Kentish Town, N.W.

**P** HOTOGRAPHER, all-round worker, requires Situation; moderate salary.—Apply "J. B.," 21, Rosebery Street, Moss Side, Manchester.

**P** RINTER desires evening employment; Bromide, Velox, P.O.P., etc.; mounting, toning; terms moderate.—"A. B.," 30, Millicent Road, Leyton, Essex.

**P** OSTCARDS.—Copyist-Retoucher disengaged; competent hand.—J. 44, 24, Wellington Street, Strand.

**R** ECEPTIONIST.—Appointment desired by young lady; good retoucher; correspondent, etc.; capable of management; excellent references.—J. 5, 24, Wellington Street, Strand.

**R** EPRESENTATIVE, with first-class connection in Southern half of England, now representing principal London house, requires an additional commission.—J. 10, 24, Wellington Street, Strand.

**R** ECEPTIONIST and Retoucher (good) requires Engagement; can take entire management; first-class references.—"M. L.," 128, Wellington Road, Bilston, Staffordshire.

**S** MART General Assistant, with 4½ years' practical experience, disengaged; good outdoor operator; knowledge of all three Platinum processes; excellent refs.—"H. S.," Vernon Road, Sutton, Surrey.

**S** MART young Operator requires Situation; has had thorough experience; commercial and technical, etc.; good references and specimens.—J. Russell, 146, Seymour Street, London, N.W.

**S** ITUATION required as first Assistant Operator and Retoucher with high-class firm; 9 years' experience; last 3 years with W. W. Winter; age 24; good refs.—Address G. Coward, 8, Barlow Street, Derby.

**W** ORKS Manager, Landscape Publishing and Photo. Postcard Works requires Re-engagement; used to large staff; good organiser; highest refs.—S. Snell, 87, Radbourne Road, Balham, S.W.

**Y** OUNG Lady (17) desires Berth as Assistant; good retoucher, spotter, and developer.—"E.," 204, Wellesley Road, Ilford.

**Y** OUNG Man (28), total abstainer, trustworthy, willing, with good knowledge of photography, requires work; studio or dark-room; London or suburbs; mod. sal.—Taylor, 24, Freegrove Road, Holloway, N.

**Y** OUNG Lady requires Re-engagement in retouching or reception room; can assist in any branch.—Address "M. B.," 56, St. Andrews, Uxbridge.

**Y** OUNG Man requires Situation as Assistant Operator and Dark-Room Manipulator; 3½ years' continual exp. at neg. making; good copyist; print in Silver, Bromide, and Carbon, etc.—Address "P.," care of 27, Gladys Road, West Hampstead.

**Y** OUNG Man (21) seeks Situation as Midget Operator and Finisher throughout; present situation 3 years; ex. refs.—Address P. Ward, c/o D. B. Seaman and Co., 17a, Irevigate, Bradford, Yorks.

**Y** OUNG Lady (21) desires Re-engagement as Receptionist-Retoucher in high-class studio; would assist finishing if required; ex. refs.—For photo, spec., etc., apply W. Sims, 22, Magdalen Road, St. Leonards.

**Y** OUNG Man (25) seeks Situation with good photographic dealers, as Salesman; 10 years' experience; smart appearance and address; ex. refs.; knowledge of sight testing and optics.—J. 34, 24, Wellington Street, Strand.

**Y** OUNG Man requires Situation as General Assistant; London preferred; good references.—"A. D.," 40, Hill View Road, Rushall, Tunbridge Wells.

**Y** OUN; Gentleman, having completed apprenticeship with high-class firm and other Xmas engagement, desires Situation in good house with opportunity of gaining experience.—Particulars, Percy, 19, Fonnereau Road, Ipswich.

**Y** OUNG Lady seeks occupation in photography; experienced; amateur photographers preferred; good-class references; retouching; spec.; small salary; photo.—Miss F. M. Whitehead, 58, Grosvenor Road, Handsworth, Birmingham.

**Y** OUNG Man, good retoucher, requires Situation in good house, where he would have opportunity to improve in operating.—J. 35, 24, Wellington Street, Strand.

# THE "AEROGRAPH."

The Improved Air Brush.  
OVER TEN THOUSAND  
IN USE.

The present model embodies all the latest improvements, the result of 15 years' experience in the manufacture of air-brushes. It is direct and simple in construction, giving the operator perfect control.

The working parts being all internal are not liable to get damaged.

There is nothing in the way to prevent colour being easily put in or changed. It is not necessary to remove the needle to clean the Instrument. One needle will last many years.

The price of the "AeroGRAPH" (as illustrated) has been reduced to **£4**, or complete, with Air - Pump, Reservoir, &c., **£5 10s.**

Every Instrument guaranteed and full instructions given to purchasers.

## DO IT BETTER!

PAUL DERRICK, the well-known advertising agent, says:—"Do it better! 'Doing it better' has made this old world a better place to live in. Doing it cheaper never improved anything."

That's our creed, too. Nowadays one must either "do it better," or else cheaper than the next man, and in photography, doing it cheaper ends, sooner or later, in "stickybacks."

Why not, for your New Year's resolution, say that you will "do it better"? We shall be glad to help you. It's because we are continually making better enlargements, better prints, better miniatures, that our work has come to be known as "The Service that helps."

Telegrams: Raines, Ealing.  
Telephone: Ealing National 64.  
" " P.O. 604.

PHOTOGRAPHIC WORKS,  
Ealing, W.

The Emblem of Quality.

There is nothing like good Printing for making money, it matters not whether it be actual advertising matter or stationery (by the way, good stationery is one of the best advertisements you can have), if it's good it will make money for you, if it's not, you had better keep the money in your own pocket.

Write us for samples of good Printing.

With the "HELIAR" Lens  
You are Certain of a  
Picture in all Weathers.

**The Lens for  
Professional Photographers.**

### THE "HELIAR" LENS.

The **Heliar**, constructed upon the calculations of Dr. H. Harting, F.R.P.S., is an unsymmetrical lens, the various parts of which cannot be used separately, or in conjunction with the corresponding parts of other focal lengths.

Between two pairs of lenses, consisting each of two lenses cemented together, there stands a single lens, and behind this single lens is placed the diaphragm. Owing to the excellent union of the light rays and the total absence of coma the proportion of aperture up to a focal length of 60 cm. is F4.5, while the field for a plate sharply focussed at full aperture is 48 degrees.

The **Heliar**, when used in conjunction with Voigtländer's Telephoto Attachments, gives excellent results.

A client writes respecting the "Heliar" Lens :—

"Many thanks for your superb catalogue. All that you say in it about your 'Heliar' Lens is perfectly correct—in fact, I find the 'Heliar' to be the best lens I have ever used."

Fully Illustrated Catalogue and "Hints on Lens" sent FREE upon application to Readers of this Paper.

## THE NEW PATENT. AIROSTYLE AIR-BRUSH

"The World's  
Finest."

For working up Enlargements,  
Tinting, Process Work,  
Show Card, and Christmas  
Card Work, &c., &c.

"Airostyle" showing needle with-  
drawn for cleaning purposes.

Always reliable, easily cleaned; it is an impossibility for any  
liquid or dust entering the mechanism.

For further particulars :—Department F,  
The Airostyle Syndicate, Limited, 35, ST. BRIDE STREET,  
LONDON, E.C.

For THE BEST STYLE of work

use the **KOH-I-NOOR Pencil**  
The Best for All Work.

People who do not know the Koh-I-Noor quality sometimes wonder why any one pays 4d. for this pencil when it is possible to get some other make for 1d. But everyone who uses a Koh-I-Noor and knows its quality says the pencil is worth even more than is asked for it. Its value is in the lead, which is prepared and compressed by a perfected process and has a fineness and delicacy of touch that deters imitation. Perfect for retouching and all Photographic pencil work. Koh-I-Noor Pencils are one price everywhere—4d. each or 3s. 6d. for one dozen. Of Stationers, Photographic Dealers, and Artists' Colourmen. Dainty Booklet on Pencils post free from L. & C. HARDTMUTH, 12, Golden Lane, London, E.C.

The new "GWYER" JET gives a pure white light, absolutely steady. It is equal in power to an electric arc, without its blueness and unsteadiness. Experts admit that no other light shows the picture to such perfection.

# DALLMEYER LENSES

Unrivalled for Quality.

## PATENT PORTRAIT LENSES

**EXTRA RAPID**  
Portrait Lenses for  
Colour and Cine-  
matograph  
Work.

for all sizes from midget to life size. They give exquisite definition, which may, however, be softened to any extent, this adjustment being made from outside the camera.

These splendid Lenses have magnificent covering power (angle  $85^\circ$ ), give perfect definition at the full aperture F/6, and are convertible, the front and back components having focal lengths respectively twice and  $1\frac{1}{2}$  times that of the complete Lens. They can be fitted to all recognised types of shutter, and are recommended as **THE BEST ALL-ROUND LENSES IN EXISTENCE.**

## THE STIGMATIC LENSES. Series II.
